Some three years or so before Bolton published his washed emulsion process the late Dr. R. L. Maddox, in the BRITISH JOURNAL OF PHOTOGRAPHY (see volume for 1871), published a gelatine-bromide process for both plates and paper, and left with the late Mr. Taylor, the then editor, specimens produced by it. This process, after improvements by others, has now practically superseded all others. For some few years after Dr. Maddox's publication the process lay in abeyance until it was taken in hand by Burgess, Kennet, Bennet, and others, including Mr. Bolton. Kennet, I think, was the first to put plates on the market, and later on their manufacture on a more commercial scale was undertaken by Messrs. Wratten and Wainwright, and by Messrs. Mawson and Swan, followed by others. Still, many photographers continued for a time to make their own. It was not till the early eighties that professionals adopted them regularly for their daily work. I need not say anything about what has taken place since that time, as the majority of my readers are perfectly familiar with the later phases of the art.

A RETROSPECT.

In the foregoing I have endeavoured to point out in as concise a way as possible the state of photography at the time of the first issue of this JOURNAL—and for some years afterwards—and the part it has played in its advancement and, more particularly, by those immediately connected with it. Now, looking back, it is a little difficult to find anything done now that was not done in the earlier days of the art. Take an instance. In 1851, at the Royal Institution, Fox Talbot, by a modification of the old slow albumen process, took a picture, which for instantaneity it would be hard to beat now. Some printed matter on a rapidly revolving wheel was illumined by the discharge of a Leyden battery, yet the lettering showed distinctly in the photograph. The moon was successfully photographed by the daguerreotype process. Collodion, albumen, collodio-albumen, and dry collodion negatives were quite equal to modern gelatine ones. About the early sixties the late Mr. England and the late Mr. Valentine Blanchard produced, by the wet collodion process, instantaneous street scenes in Paris and London that have not been surpassed. My friend, Mr. Frank Haes, about that time, or before, took a series of photographs of the animals in the "Zoo" that will hold their own against most modern work of the same subjects. Breaking waves, and on large plates, too, were also taken by many of the older workers, and they will yet compare very favourably with those taken on gelatine plates. But at what trouble, cost, and inconvenience were these results obtained! Cumbersome portrait lenses had to be employed, and then the work could only be done in the best of light. When this is considered these results may be looked upon, successful as they were, very much in the light of *tours de force*. Now the same results are daily obtained with the most portable of apparatus, and with lenses of no very great rapidity. Furthermore, all the plates employed, and the paper for printing, are now to be purchased ready for use. What a contrast! Was such a thing dreamt of—even by the most sanguine photographer—when the BRITISH JOURNAL was first published, just fifty years ago?

The Story of the "British Journal of Photography."

By the Editor.

CHAPTER I.—THE LIVERPOOL JOURNAL.

THE establishment of the "Liverpool Photographic Journal," a facsimile reproduction of the first page of which forms the introductory illustration to this article, was the direct consequence of the great success that attended the institution of the Liverpool Society in the year 1853. The members appear to have been hard workers. I take the following extract from a paper on "Historical Notes of what Liverpool has done in

The Society subscribed £275, and appointed trustees to see laid out in the education of his children. Mr. Thomas Higgin has devoted his efforts to the department of microscopic photography with great ardour and enthusiasm, and produced work of the highest possible merit, which have not been excelled. One member reached such a high state of perfection in the art that Mr. Osmond R. Green. His pictures were large, some twenty-four inches by eighteen inches, and, though taken above twenty years ago, by the collodio-bromide process, they comman-

the Art-Science of Photography," which appeared in this journal of February 3, 1888. The author was Mr. Jas. A. Forrest, whose portrait appears above.

"Mr. J. T. Foard did great work in the Society by supplying it with papers of high-class merit. Mr. George Thomas, in 1853, took photographs of the New Brighton fort from the Lancashire shore, three miles distant, using the object glass of a five-foot telescope, the difference between the chemical and visual foci being a quarter of an inch; this illustrated the advantage of photography for military purposes, and it was adopted by the Government during the Crimean war. Mr. John Glover was an indefatigable experimentalist, but, being of a weak constitution, he became a victim to his own ardour.

admiration to the present day. Frank Howard, an artist of considerable celebrity, was also an active member. Mr. John M'Innes, the first and most successful discoverer of the method of coating ships' bottoms with material to withstand the action of plants and barnacles adhering to the iron, rendered great service to the Society on many occasions."

With such a fine spirit of active enthusiasm animating its members, it was no wonder that the Society did good practical work, and that in a very little while it should set up a journal of its own in which its proceedings and transactions could be recorded. So it came to pass that the "Liverpool Photographic Journal" was published. The proprietors were three members of the Society, Mr. James Newlands, the Liverpool Borough

ADDRESS.

THE LIVERPOOL PHOTOGRAPHIC SOCIETY; in putting forth a Journal of their own, rest their claims to public support upon the widely extending interest in the several branches of Photographic art—the daily progress that is being made by the practical members of their own Society, and other Photographers elsewhere. The admirers of the art naturally desire to have more particulars, and the practical operators more full and precise records of the suggestions, experiments, and successes in various parts of the world, than can possibly be afforded by a newspaper devoted to general information. The *London Photographic Journal*, though furnished with the Proceedings of the Liverpool Society from the commencement, has not been able to find room for them; a part only of the May Meeting being given in the September number. The Glasgow Photographers obtain their information of our Proceedings through the medium of American newspapers!

An exhibition of Photographs has been proposed to take place during the visit of the British Association to Liverpool. In conjunction with this, the Liverpool Photographic Society have offered premiums for the best specimens of the art produced by their own members. A premium has also been offered by the British Association for the Best Photograph of the Moon—for which it is expected our resident Photographers will compete.

The award of the premium offered by our Society will be influenced, if not decided, by the opinions of the British Association; but it is desirable that public taste should be brought to bear upon it; and to cultivate the true appreciation of the beauties of the Photographic art—the qualities most valuable, most to be admired—the Society propose this publication, in which not only all the Papers read at the meeting will be published, but the discussions upon them, in the course of which individual observations and suggestions occur of the highest importance, though they may not be appreciated at the moment in consequence of some other matter being the absorbing point of interest.

The Liverpool Society have therefore deemed it expedient to have a Journal of their own, commencing with the report of the first meeting in the new year. But that the records preserved may be complete, a *resumé* will be given of what has already been done by the Society, with such Papers as may be considered interesting of those which have been read at previous meetings. The Proceedings of the London Society, and of independent operators at home and abroad will be given, with everything that can be obtained to furnish our readers with a complete account of the state and progress of the art in all its various branches.

Various forms of camera adapted to Photographic operations, have been exhibited by Mr. MACKINLAY, Mr. WOOD, Mr. ATKINSON, and others, members of the Society, of which

Engineer; Mr. Christopher Bell; and Mr. James Alexander Forrest, whose portrait is here given. The editor was Mr. Charles Cory, who appears to have been an able and dignified occupier of the chair. So successful, indeed, was Mr. Cory in his editorial selection that extracts from the "Liverpool

Journal" of 1854, which we reprinted a few weeks ago, aroused widespread interest amongst modern photographers, who hitherto no means of informing themselves of the very advance to which applied photography had advanced half a century ago.

PHOTOGRAPHIC PORTRAITS.

W. B. BARKER, Chemist, (late of Grange Lane, Birkenhead.) Member of the Pharmaceutical Society of Great Britain, begs to apprise his Patrons and the Public generally, that he has now arranged to devote himself entirely to the art of taking **PHOTOGRAPHIC PORTRAITS**, and that he has succeeded in obtaining one of the most eligible Rooms in Liverpool, for Photographic purposes, at

NORTH CRESCENT, CHAMBERS, 3, LORD-STREET, third door from the top, on the right hand side going up; and that he has now fitted it up in the most artistic manner, for producing perfect Photographic Portraits, both single and in groups.

His extensive experience in Photography for the last two years, and his practical knowledge of Chemistry, have enabled him to introduce many important improvements, which, combined with his increased facilities for producing artistic effect in his new Rooms, will enable him to sustain that *very high character which his Pictures have already acquired*.

Amateurs supplied with Iodised Collodion and Pure Photographic Chemicals.

JOHN H. & SAMUEL JOHNSON, Operative Chemists, 7, Church-street, Liverpool, have always on hand a large Stock of the purest and most carefully prepared **PHOTOGRAPHIC CHEMICALS**, & every other material for the practice of Photography. Spirit Lamps, Mortars and Pestles, Funnels, Scales and Weights, Graduated Measures, Stirring Rods, Beakers, Dippers, Gutta Percha Baths, Trays, &c.

CHEMICAL APPARATUS of every description, and **GUTTA PERCHA** Articles made to any pattern.

CHAPTER II.—HENRY GREENWOOD.

two years the "Liverpool Journal" pursued a career of photographic wisdom and utility, amusingly varied, now and then, by the exchange of polite compliments with its esteemed London contemporary, the official organ of the London Photographic Society. The origin of the rivalry between London and Liverpool in matters of photographic journalism is, at this distance of time, rather difficult to discover and set forth, even were one persuaded that the game is worth the candle (I do not, myself, think it is); one must therefore simply be content to note the fact and pass on, remarking, by the way, that this rivalry led to a visit to the Law Courts and a final inter-

PHOTOGRAPHY. Greenwood was in many respects a remarkable man. As a printer and stationer he showed great business shrewdness and capacity for work, but it is probable that in his supernumerary position as editor-in-chief of his own journal he shone in the most favourable aspect. A practical printer and journalist, with an attractive, if somewhat ornate, literary style, he often supplemented the work of his editing with interpellated articles of great merit. Chiefly he chose subjects of a personal nature, such as a farewell, a death, etc. As a sub-editor his equal could, perhaps, not be found, and there is no doubt that the JOURNAL owed a vast deal to his

HENRY GREENWOOD,
Proprietor of the BRITISH JOURNAL OF PHOTOGRAPHY, 1857-1884.
Died December, 1884. Aged 66.

ment of the hatchet at the end of 1859. And all over the title of a paper.

Amateur proprietorship and amateur editing not spelling commercial success *in excelsis*, the copyright of the "Liverpool Photographic Journal" passed, about 1857, into the hands of the printer, Mr. Henry Greenwood, of Liverpool.

Until the day of his death, in the year of 1884, Mr. Greenwood kept a firm hold upon the property he had thus acquired. As the reproductions in the next chapter will show, it passed through many evolutionary changes before finally assuming, on January 1, 1860, its permanent title of the BRITISH JOURNAL OF

sleepless vigilance and overlooking during the many years it was under his control. There are many still living who, I am sure, will appreciate this brief sketch of a delightful personality, who made an idol of his paper; who was a strict and honourable man of business, a firm and faithful friend, and a kindly-hearted man. I knew Greenwood between the years 1881-1884, and his memory is one that I cherish with sincerity. He was a fine example of the success of the personal equation in business, and his unwearied devotion to the interests of the JOURNAL supplies one with a lesson without which one would be distinctly the poorer.

CHAPTER III.—THE EVOLUTION OF A TITLE.

THE PHOTOGRAPHIC JOURNAL.

No. 85, Vol. VI.—JANUARY 1, 1859.

We trust that in making our appearance before our readers in a new guise, they may approve of the change that has taken place, and consider it an improvement as well as an alteration. Like the ladies of the present day, we have greatly enlarged our skirts—and like them, of course, must also regard the arrangement—as an embellishment. Least more engaging costumes, however, should have so modified our appearance as to cause some risk of our being mistaken for a stranger, we must retain our readers that we are but "an old friend with a new face," and we hope not only to retain friendships already formed, but to convert acquaintances into friends, and strangers into acquaintances.

It has been a matter of very careful consideration with us how we may become still more useful to our numerous supporters than we have been hitherto—some of our intentions we have already indicated, and we have now further to mention, that we shall commence a series of historical articles; first, for the benefit of those still on the threshold of photographic acquaintance; and second, for more advanced students, of causing history details, descriptive of all the most approved methods of operating, as ascertained up to the present time; for we cannot but feel that photography of to-day is a very different thing from photography as it was a couple of years, or even one year ago—so many labourers are in the field, and so much has been achieved, that it is almost impossible for those not more than commonly interested, to keep pace with all the knowledge that has been acquired in the various ramifications of practical photography.

By this arrangement, it is hoped, that all classes of our readers will find their tastes gratified—the novice and the adept, "the mere man of taste and process, and technically," as we have ourselves been contemptuously styled—the man of science and the man of art—in short, we wish to make our pages like the fountain at which all will find something to quench their thirst; and our aim will be to endeavour to follow the wise steward, and "give all their dues in due season." It has been suggested to us, that the single attention which we have found it requisite to make in our designation, may possibly tend to cause some confusion with, and inconvenience to, the public, by confounding us with *The Journal of THE PHOTOGRAPHIC SOCIETY*. Now, although we do not think there is any fear on this head, the names of the Photographic Society being so very distinctive, and photographers, as a class, are men of discernment, we always having liberto maintained (and we trust ever to do so) most unflinching alliance with the colleagues of the oldest public-spirited devoted exclusively to our avocation, we therefore, unhesitatingly make the present opportunity of disclaiming any intention whatever, of an attempt to assume an attitude of hostility, or to deceive the public in any way. In proof of this assertion, we appeal to the number now before our readers as evidence that nothing in size, style of heading, general aspect, or arrangement of matter, is there any resemblance whatever to the publications of the Photographic Society.

With regard to our Title, we have merely altered the order in which the words were formerly arranged, and added one or two more.

With a hearty wish that our readers may find the coming year prove a prosperous one, both photographically and otherwise, we pass to the "order of the day."

It appears to be a debatable question, whether of the twin, photographic engraving or lithography, will be the first that will be practically applied to book illustration. As regards the former, in addition to the productions of Mr. Fox Talbot, now before the public, we have in another column a communication on the subject from our esteemed correspondent, Mr. Burnett. Now, although photo-lithography, as it has been termed, may, and probably will, eventually become developed into the more important operation of the two, we are strongly of opinion that lithography, even in its present condition, is sufficiently advanced to render efficient service, with a very small amount of assistance from the hand of the draughtsman. At the last meeting of the Photographic Society, Mr. Malone expressed an opinion in accordance with our own; and since then, we have seen produced by an amateur photographer, acquainted with the lithographic art, as his first essay in this direction, a result that not only astonished us, but that requires only a few touches to convert it into an excellent picture. It must be borne in mind, that there is a vast difference between the assistance of a lithographer and that of an engraver—almost any capable of handling a pencil can readily qualify himself for one, whilst that is far from being the case with the other.

It may be objected that we are now addressing the very thing we have formerly condemned, viz.—the "enriching" of photographs; but we by no means assent to such an imputation; the cases are widely different. We object to "touched" photographs when judging of their respective merits; as obtaining credit upon false pretences. We do not advise or commend to any the attempts to impose upon the public profits from the sale of photographic stones that have been submitted to the hand of an artist as pure photographs; but we do approve of the imitable, into the lithographic art. We may have more to say about this in a future number.

We were pleased to notice the other day a very useful signification of photography. At the establishment of an auctioneer, and estate agent of the name of Englebert, in Clement's Lane, London, are a number of paper prints from negatives of various houses, &c., that are to be let or sold by the auctioneer.

No exception, however, merits, can possibly give so good an idea of the appearance presented, as a single glance at these photographs; and we feel convinced, that a general adoption of the Plan would be followed by an immense saving of trouble to the customers, and consequent increase of business to those who render such facilities.

At the meeting of the French Photographic Society, held on the 29th October last, MM. Davanne and Girard presided.

BRITISH JOURNAL OF PHOTOGRAPHY, a title which has known alteration in forty-four years.

For some years the paper, in the same size and shape it at present bears, was issued fortnightly. Subsequently it first published weekly, being successively enlarged from twelve, and from fourteen to sixteen pages. The price reduced in 1859 from threepence to twopence, and in 1901 text portion of the paper was permanently enlarged to two pages. But the general form and style of the paper have varied but little from that of the issue of January 1, 1850, when "B.J." definitely placed itself in the forefront of photographic journalism.

CHAPTER IV. THE ALMANAC.

It is commonly supposed that the first "Almanac" was a large volume, the dimensions of which were such that the book could be easily slipped into the waistcoat, like a card-case in fact. This is an error. The very first "Almanac" took the form of a folding sheet calendar which was presented with the number of the volume of the JOURNAL for 1859. This experiment was not repeated. Something more ambitious was attempted, and so it was that the little pocket-book contained calendar matter, brief articles on photography, and other literary fare was presented gratis to the readers of the JOURNAL. The "Almanac" in this form, size, and style, was so published for four years, and in 1865 it was issued in crown octavo size and bound in green cloth. For forty years the characteristic external features of the book have not been changed.

The illustrations will convey to the reader a good idea of the comparative features of the "Almanac" for 1861 and 1904. The latter weighs between three and four pounds, and numbers over 1,600 pages, which are roughly divisible into 1,000 pages of advertisements and 600 pages of text. Twenty-five thousand

Facsimile of Page 1 of "The Photographic Journal."

EDITED by a committee of the Society, the "Liverpool Photographic Journal" continued its career down to the year 1856. In 1857, probably upon the acquisition of the copyright by Mr. Greenwood, the title was changed to that of the "Liverpool and Manchester Photographic Journal." At this stage, what one may, without intentional disrespect, term "amateur editing" was dispensed with, and the control of the paper placed in professional journalistic hands. The JOURNAL had now reached the first crisis of its commercial fortunes. Not unnaturally desirous of addressing a larger public than that of Manchester and Liverpool combined, Greenwood took the bold course of converting the title of the paper into that of "The Photographic Journal." But the sanguine young proprietor had overlooked the prior claims of the London Photographic Society in the matter, that Society then, as now, having a legal claim to the exclusive use of the title "The Photographic Journal," and so, as the result of some litigation, Greenwood was compelled to climb down. Later in the same year he expressed his intention of styling his paper "The Journal of Photography," but objection being taken by the London Photographic Society to this title, Greenwood again gave way, and on January 1, 1860, headed his paper the

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 109, Vol. VII.—JANUARY 1, 1860.

The Title announced in our last not having given entire satisfaction to the Proprietors of the Journal of the Photographic Society, we so far amend their views as to add to our amended title the word "British" as a prefix. The present Number, therefore, appears before the public as THE BRITISH JOURNAL OF PHOTOGRAPHY—a title at once distinctive, and yet bearing the impress of its former existence, as it is, at our understanding with the Proprietors of the London Society's Journal will finally allow.

In order to prevent confusion to our readers, and further to the arrangement of our plans, we have agreed between us that the appearance and general aspect of the Journal will be so altered as to distinguish it from the other contemporary, that hereafter special attention were particularly directed to the point we question whether there are many of our readers who will be so desirous of changing. In this we believe we are acting primarily for the interests of all parties; for there never was a question of dispute relative to any supposed resemblance between this Journal and that of the "Photographic Society," but upon the words of the title only, and this being now completely set at rest, we hope to maintain the relations of unity and goodwill with our older contemporary, that hereafter never been interrupted before the one point of difference now removed. May we both enjoy a long career of usefulness.

We find on looking over our summary of the past year's photographic history that we have inadvertently committed an error in attributing to Mr. Hensch the credit due to Mr. Thomas J. Wanders, the accomplished Secretary to the London Photographic Society, for testing the value, as a photographic agent, of Dr. Schwebel's system of collodion, the value of exposure here the same from our having trusted to our own record of reference, as we did in the case of the paper, which have already appeared in our pages, and from having Mr. Hensch's name so familiarly before our mental vision in connection with other

might by Mr. Hensch's method produce enlarged negatives by the operation direct in the camera; and in this case the increased exposure and chances of failure would be so comparatively little importance. The arrangement we are now proposing is substantially the same as formerly, but there is a slight change in the order of the respective manipulations introduced.

As regards the importance of printing direct from negatives by contact, instead of employing the use of an opaque paper from which, negatives in the end-ergon camera, we were much interested by a remark made by Mr. J. B. Smith, of Bristol, in a conversation which recently took place between us. This gentleman pointed out that artistic effects are much more under control in the former case, especially as regards the high-contrast of portraits.

As a precaution, we imagine not likely to be called in question. The same upon several previous occasions drawn attention to the desirability of refraining with respect to cameras, which, as generally constructed, are too heavy and clumsy, to any thing of sundry other defects which many of them are afflicted with. We have recently examined a novelty in camera of very considerable merit, lately introduced by Mr. A. J. Mahabish, of Birmingham—a camera which first we named as we did not at all anticipate would turn out to be of any great importance, but which we now regard in a very different light. The camera, which is so constructed of metal—viz. brass, electro-plated, or german silver; and the inventor's contrivances, as to this, &c., the probability of constructing it also in silver. The advantages are practically rigidity, cleanliness, lightness, compactness, and freedom from the liability of becoming fogged either by heat or moisture. As yet we have only seen a camera adapted for taking stereoscopic negatives constructed upon this principle, but we see no reason why they should not be equally successful upon a larger scale. It might be objected that the trial is easily kept out of shape—in fact it was one of the first objections that occurred to us, but when we see that

copies of the book are annually sold, usually before the date of publication. The "Almanac" has created for itself quite its own curiously special little public. The book passes into the hands of everybody who is anybody in the photographic world,

the "Almanac," upon the contents of which they contentedly feed for twelve months. There are many hundreds of such photographers; if, indeed, there are not some few thousands.

Probably there is no photographic book published which .ay

The Old Order and the New: The First Four Volumes of the ALMANAC, bound in one Volume (on top) and the Last Four Volumes.

The Old Order and the New: Title Pages of the ALMANAC for 1861 and 1904.

and also into the hands of many of whom the photographic world never hears. These are chiefly English photographers living abroad or in the Colonies, who buy and read no photographic publication all the year through, preferring to wait for

by day, week by week, and month by month, is so frequently consulted by photographers and those interested in photography as THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, which forms the subject of the illustrations to this chapter.

CHAPTER V.—GEORGE SHADBOLT, GEORGE DAWSON, SAMUEL HIGHLEY.

BETWEEN the years 1857 and 1864 the JOURNAL was fortunate in securing the services of several able men of science to conduct its pages. Of these, perhaps one of the ablest and most scholarly was Mr. George Shadbolt. Mr. Shadbolt occupied the chair for about seven years between 1857 and 1864; and it was only the growth of his private business which necessitated his retirement from photography and its journalism. With Mr. Shadbolt's disappearance the BRITISH JOURNAL OF PHOTOGRAPHY, which had hitherto been issued fortnightly and consisted of eighteen pages, became a twelve-page weekly, and the publishing and editorial offices were removed from Liverpool to London. Mr. Shadbolt, who was one of the founders of the Photographic Society of London, now the Royal, devoted much attention to the optics of photographic lenses and to photo-micrography; and upon those themes his contributions to the JOURNAL during his editorship were valuable and frequent. He is also said to have been the first to take a micro-photograph, and, so far back as 1858, suggested the practicability of a triple lens "consisting of single convex lenses at each end of a short tube corrected by a concave of flint glass in a central diaphragm." He was a Vice-President of the North London Photographic Association before which body we find him reading a paper, in May, 1863, on "Open-air Portraiture."

The pages of the JOURNAL for 1854 testify to the great esteem in which Mr. Shadbolt was held by those with whom he was associated, and some months after his retirement he was the recipient of an elegant silver épergne in recognition of his services to photography. The following gentlemen formed the deputation from the Testimonial Committee at the presentation, which took place in July, 1865: Messrs. Shave, E. W. Foxlee, Melhuish, G. Wharton Simpson, J. Traill Taylor, Hill, H. P. Robinson, and Barnett. An editorial note in the JOURNAL of July 7, 1865, expressed admiration of Mr. Shadbolt's varied acquirements as a scholar and a man of science; sorrow that he should have felt compelled to resign a position the duties of which he filled with dignity and efficiency, and regret at his withdrawal from the field of photographic research, while yet in the

full maturity of his mental powers. There are photographers still living who speak in terms of the highest appreciation of the late Mr. Shadbolt's great ability as an editor and a student of photographic science.

GEORGE DAWSON.

George Dawson, at the time of his death in 1897, was in his seventy-seventh year, and will be remembered by reason of his long association with King's College in the capacity of Professor of Photography. He was formerly one of the Editors of the BRITISH JOURNAL OF PHOTOGRAPHY, and was joint author, with the late Thomas Sutton, of the "Dictionary of Photography." He also edited one of the earlier editions of Hardwick's Photographic Chemistry.

SAMUEL HIGHLEY.

Mr. Samuel Highley, F.C.S., who died at the end of 1900, was, nearly forty years ago, an Assistant Editor of the Journal, and on the title page of the "Almanac" for 1861 his name appears as the Editor. He interested himself in popularising optical projection for scientific purposes, and some of his articles on the subject, written at about the date mentioned, are so admirably expressed that, if reprinted now, they would pass muster as the work of a modern author newly emphasising the value and advantages of the lantern in the lecture room. A full list of Mr. Highley's public contributions to general scientific knowledge lies before us in the form of a printed pamphlet. Besides photography, mineralogy and microscopy appear to have been amongst his subjects. He was a prolific writer and a man of varied tastes and occupations. Mr. Highley, who was seventy-five years old when he died, was secretary of the Photographic Society of Great Britain in the 1857, and in his time held many other scientific and journalistic offices. He passed a varied, busy, and useful life, and his record, if unfamiliar to the present generation, was as creditable as it was full.

CHAPTER VI.—SIR WILLIAM CROOKES.

SIR WILLIAM CROOKES, F.R.S., who, in the early sixties, acted as one of the editors of the BRITISH JOURNAL OF PHOTOGRAPHY, writes, after all these years, in the most pleasant manner of his association with the JOURNAL. I am indebted to him for the appended biographic details and the excellent portrait. Sir William Crookes, F.R.S., P.P.C.S., Past President of the Institution of Electrical Engineers, who was born in London, June 17, 1832. He entered Royal College of Chemistry in 1848 as a pupil of Dr. Hofmann, and gained the Ashburton Scholarship in 1849. In 1850 he became junior, then senior, assistant to Dr. Hofmann, which position he retained till 1854, when he obtained the appointment of Superintendent of the Meteorological Department of the Radcliffe Observatory, Oxford. He was elected a Fellow of the Royal Society in 1863.

Mr. Crookes founded the "Chemical News" in 1859, of which paper he is still the proprietor and editor. In 1861 he announced to the world his discovery of thallium, a new metallic element, and from that date to 1864 he worked almost entirely on the elucidation of the chemical properties of thallium and its compounds, communicating the results of his investigation in several papers to the Royal Society, the Chemical Society, and the "Chemical News." In 1864 he became editor of the "Quarterly Journal of Science." It is stated that Mr. Crookes was the first to apply photography to the investigation of the solar spectrum; but his earlier researches were so numerous

that it is impossible to refer to them all. An authority on sanitary questions, his views have been laid before the public in two pamphlets—"A Solution of the Sewage Question," and "The Profitable Disposal of Sewage." Mr. Crookes, in conjunction with Dr. Odling and the late Dr. Tidy, investigated the sanitary condition of the water supply of London. A long series of original investigations must be credited to Mr. Crookes. These investigations gave us the radiometer, and led to the vacuum experiments so valuable in electrical work. In 1875 the Royal Society bestowed on him the royal medal for his researches on repulsion resulting from radiation, and the discovery of thallium. In 1879 the Royal Society published in its "Philosophical Transactions" records of Mr. Crookes's experiments on "Molecular Physics in High Vacua," comprising "Magnetic Deflection of Molecular Trajectory," "Laws of Magnetic Rotation in High and Low Vacua," and "Phosphorogenic Properties of Molecular Discharge." In the same year appeared a further paper on "Repulsion Resulting from Radiation." The subject of his second Bakerian lecture to the Royal Society was "Illumination of Lines of Molecular Pressure, and the Trajectory of Molecules." In the form of a lecture delivered before the British Association, under the title of "Radiant Matter," he compressed his researches on the electric discharge in high vacua. In 1880 the French Académie des Sciences bestowed on Mr. Crookes an extraordinary prize of 3,000 francs

Sir William Crookes, F.R.S., Editor of the BRITISH JOURNAL OF PHOTOGRAPHY. 1861.

and a gold medal, in recognition of his discoveries in Molecular Physics and Radiant Matter. In 1881 Mr. Crookes acted as a juror at the International Exhibition of Electricity in Paris. In this official position he was not entitled to a medal, but in the official report his fellow jurors, after discussing the merits of four systems of incandescent lamps, declared—"None of them would have succeeded had it not been for these extreme vacua which Mr. Crookes has taught us to manage." It is well known that the value of an incandescent lamp depends greatly upon the perfection of the vacuum obtained; and in his paper before the Royal Society in 1877 Mr. Crookes concluded that the most perfect vacuum then obtained, in which the pressure was only 0.4 millionth of an atmosphere, contains in each cubic centimetre no less than 250,000,000,000,000 molecules of air, as compared with Mr. Johnstone Stoney's estimate of the number of molecules contained in a cubic centimetre of ordinary air, which is 1,000,000,000,000,000,000 (one thousand trillions). Mr. Crookes's house, 7, Kensington Park Gardens, is said to be the first house in England lighted by electricity, his private installation of gas engine, Burgen dynamo, and incandescent lamps of his own make dating from the latter part of the year 1881. In 1883 Mr. Crookes delivered the Bakerian lecture for the third time before the Royal Society, the subject on this occasion being "Radiant Matter Spectroscopy: The Detection and Wide Distribution of Yttrium." In 1885 the Society of Arts awarded him the Ferguson medal for "his improvements in apparatus for the production of high vacua, and for his invention of the radiometer." In 1886 Mr. Crookes was elected President of the Chemical Section of the British Association; and at their Birmingham meeting that year he delivered an address in which he propounded some novel speculations on the probable origin of the chemical elements, showing that the balance of evidence was in favour of the view that our so-called elements have been formed by a process of evolution from one primordial matter. In 1887 he delivered a Friday evening discourse before the members of the Royal Institution, on the "Genesis of the Elements." In his address to the Chemical Society in 1888, on taking the president's chair, Mr. Crookes still further elaborated this theory, bringing forward numerous arguments, many of them based on experiments, to prove that the chemical elements are really compound bodies. These views were again urged, with numerous experimental proofs, in his presidential address to the same Society in 1889, and they are now generally accepted by chemists. In 1888 Mr. Crookes was awarded the Davy Medal of the Royal Society, for his Radiant Matter researches. Mr. Crookes was President for 1891 of the Institution of Electrical Engineers. He received the honour of knighthood in 1897, "in recognition of the eminent services he has rendered to the advance of scientific knowledge during her Majesty's reign." In 1898 he was President of the British Association for the Advancement of Science. In 1899 the Society of Arts awarded him the Albert Medal for "his extensive and laborious researches in Chemistry and Physics; researches which have in many instances developed into useful practical applications in the arts and manufactures."

CHAPTER VII.—JAMES MARTIN.

JAMES MARTIN became Assistant Editor of the "B. J." and Editor of the "Almanac" in 1863. He has written in reply to a request for a personal reminiscence of his connection with the paper: I acknowledge with pleasure your interesting note, recalling as it does my pleasant associations with the BRITISH JOURNAL OF PHOTOGRAPHY, its courteous and alert editor, George Shadbolt, and its genial and enterprising proprietor, Henry Greenwood, whose hospitality it was my privilege to enjoy at his Liverpool residence in the early sixties. It is gratifying to note that the traditions of unwavering courtesy

and cordiality which characterised the intercourse of editor and contributors at that time is continued to the present day, by which I feel encouraged to respond to your invitation. You ask for (1) notes of my experiences and (2) some biographical details.

1. My Experiences.—So far as concerns the present, they are those of most who labour at photography for a livelihood, and can have little special interest for your readers; but the jubilee of the journal awakens memories and suggests contrasts. I recall with admiration such names as Hardwich, Major Russell Manners Gordon, Rev. F. F. Statham, *et sic genus omnes*, enthusiasts who pursued the study of photography regardless of loss and irrespective of gain, and achieved distinction in their un-

JAMES MARTIN,

Assistant Editor of the BRITISH JOURNAL OF PHOTOGRAPHY, and Editor of the "Almanac," 1863.

selfish courses, contrasting most favourably with the present tone of its followers, with whom (so far as my limited acquaintance may permit the judgment) commercial gain is the potent stimulus. I trust I may be pardoned if I am wrong.

2. Biographical Details.—As connected with the BRITISH JOURNAL OF PHOTOGRAPHY, I was privileged in 1863 to edit the Almanac for that year. It was presented, not sold, to the readers of the journal, and I know of no more forcible illustration of the strides made by photography in public appreciation than to contrast the Almanac of 1863 with that of 1903; it is as Lilliput to Brobdingnag!

Yielding to your solicitation, I may further mention that my Alma Mater is the Pharmaceutical Society of Great Britain, of

which institution I am an associate by examination, and where as laboratory assistant I acquired such a knowledge of chemistry as enabled me for the appointment of assistant to the late Professor Woodward, whose memory I cherish with the highest respect and gratitude. A brief engagement with a firm of manufacturing chemists at Worcester* was followed by a longer one with the firm of George Knight and Son, of Foster Lane, where I remember to have sold pyrogallic acid at ten shillings a dram and posulphite of soda at three shillings a pound. By an engagement with Beard and Son, of King William Street, I became an expert in the Daguerreotype process, of which I retain an interesting series of examples.

A voyage round the world and a few years' stay in the Australian goldfields interrupted my connection with our art science, but on resuming I became a constant attendant at the meetings of the three pioneer photographic societies, whose proceedings I reported for the BRITISH JOURNAL OF PHOTOGRAPHY, to the pages

* Whitfield and Son.

of which I also contributed a long series of articles on photographic chemicals and fortnightly translations from the French photographic journals, chiefly "Le Moniteur de la Photographie."

Other literary labours were my revision of the article "Photography" in "Orr's Circle of the Sciences" for Messrs. Houlston and Wright, and my response to the invitation of Messrs. W. and R. Chambers to contribute the articles included in the section "Photography" in their Encyclopædia, which was accomplished to the satisfaction of its distinguished editor, Andrew Findlater, LL.D.

I also had the honour of reading a paper, "On a Self-recording Aneroid Barometer," at the meeting of the British Association for the Advancement of Science at Exeter in 1869.

My four small scientific manuals, the aggregate sale of which exceeds a hundred thousand copies, are fairly well known, and their titles indicate their scope—"The Magic Lantern," "The Model Steam Engine," "The Aneroid Barometer," and "Weather Warnings for Watchers."

CHAPTER VIII. JOHN TRAILL TAYLOR.

In 1864 the publishing and editorial offices of the JOURNAL were removed to York Street, Covent Garden, London, and in these offices, dear and hallowed to many of us by their associations, the paper entered upon a career of prosperity and progress which has known no interruption. It was in this year that Taylor, long valued contributor to its pages, assumed an editorial position in the JOURNAL, which was to continue without a break for fifteen years.

John Traill Taylor was born at Kirkwall, in the Orkneys, on January 23, 1827. As a youth he was attracted to, and practised the Daguerreotype process, and, in the intervals detached from the pursuit of his profession as a watchmaker, developed great aptitude for the study of the chemistry and optics of the then very young art of photography. We have frequently heard him smilingly remark that in those days there were no photographic papers to help a young photographer out of his difficulties, and that of the optics of photography, a field in which he was subsequently destined to gain considerable prominence, it was difficult, if not impossible, to acquire knowledge from others.

A long residence in Edinburgh was the means of bringing Mr. Taylor into contact with Sir David Brewster, Henry Fox Talbot, Mungo Ponton, Piazza Smyth, R. H. Bow, Thomas Davidson (the optician), and other noted workers of forty years ago, by whom he was highly esteemed for his knowledge of photography and his abilities as an experimentalist and writer. For some time he was on the staff of the "Scotsman" and other Scotch newspapers, and dated his first association with photographic journalism from about the year 1856, when he established an ever-circulator magazine devoted to photography, and called the "Photographer," many extracts from which will be found in the earlier volumes of "Photographic Notes," edited by Thomas Sutton, B.A., between whom and our late friend a warm regard subsequently sprang up.

It was in the year 1859 that Mr. Taylor became a regular contributor to this journal, and thus started a connection that was only to terminate with his death. Five years later—that is, in 1864—on the retirement of Mr. Shadbolt, he was appointed Editor, a position he filled for the succeeding fifteen years. In the early part of 1879 he vacated the chair for the purpose of taking a commercial appointment in the United States, and before his departure a numerously-attended farewell dinner was given, and a handsome gold watch presented to him, as marks of the esteem in which he was held by the photographic public. Circumstances deciding him to abandon this new position about a year after his arrival in New York,

he resumed his connection with photographic journalism, taking up the editorship of the "Photographic Times" (New York), which rapidly prospered under his skilful direction, and also

JOHN TRAILL TAYLOR,
Editor of the BRITISH JOURNAL OF PHOTOGRAPHY,
1864-1879 and 1886-1895.

contributing to this journal, of which, together with its "Almanac," he once more assumed the editorship on January 1, 1885.

Some of Mr. Taylor's optical writings were published in

book form a few years ago, but they are not fully representative, either of the extent of the depth of his knowledge of the subject. But, happily, it is not necessary for us, in dwelling upon the vast store of his photographic knowledge and experience, the directness and simplicity of his literary style, and his sagacity as an editor, to do so specifically or in detail—the volumes of the *JOURNAL* and the “*Almanac*,” for over one-third of a century, eloquently tell the story of his life's work, and constitute what we know he himself would regard as his best, most enduring, and proudest memorial.

Outside his journalistic labours, the world of photography has cause to be grateful to Mr. Taylor for many efforts and labours in its behalf. Over thirty years ago he was, we believe, one of the founders of the Edinburgh Photographic Society. In London he was for a long time a member of the

Council of the Royal Photographic Society; trustee of London and Provincial Photographic Association; President of the North London Photographic Society; and an honorary member of the Photographic Club and the Camera Club. He was formerly President of the Photographers' Benevolent Association, and was the founder of the Photographic Convention of the United Kingdom. Many other photographic societies in America, in France, and other parts of the Continent, claim him as a member.

The popularity Mr. Taylor enjoyed among the many thousands of photographers with whom he came in contact during the course of his long career, is not difficult to understand. He was ever genial, communicative, and kind hearted, ready to help with advice, counsel, or information; the beau idéal of fact, of natural bonhomie and good humour.

CHAPTER IX.—W. B. BOLTON.

1864 was a great year for the *JOURNAL* in many respects. Besides witnessing the managerial and editorial changes to which I referred in a previous chapter, it saw the publication, over the names of W. B. Bolton and B. J. Sayce, of an epochal paper, which dealt in a practical manner for the first time with a method of emulsifying the silver salts in collodion

paper pointed the way to what was destined to come at no distant date.

PHOTOGRAPHY WITHOUT A NITRATE OF SILVER BATH.

Without entering into the preliminary investigations which led to this discovery, the secret of the whole consists in converting simply bromised collodion into what we will for convenience designate “collodio-bromide of silver,” by the addition of the combining equivalent of nitrate of silver to the previously bromised collodion.

To reduce this to practice we prepared bromised collodion as follows:—

Alcohol	$\frac{1}{2}$ ounce.
Bromide of cadmium and ammonium.....	3 grains.
Pyroxyline	2 grains.
Ether	$\frac{1}{2}$ ounce.

Well filtered.

We then took an ounce phial, placed therein four grains of pulverised nitrate of silver, which we dissolved in two drops of distilled water; then covered the bottle with a perfectly non-actinic coating of brown paper, and in a yellow light added an ounce of bromised collodion. The mixture at once produced a milkiness, which does not disappear; we then shook the bottle and coated a clean glass—previously tipped at the edges with benzine and India-rubber solution—with the collodion, without even allowing it to settle, and allowed the film to set in the ordinary manner; then placed the plate, face upwards, in a dish of water, and when the greasy appearance vanished, rinsed under the tap for a few seconds; then poured over the film the ordinary fifteen-grain solution of tannin, worked it into the film for about one minute, drained, wiped the back with blotting-paper, and dried rapidly in a kitchen oven.

This plate was exposed the following day for thirty seconds using a Ross's four inches and a half focus single lens, small diaphragm, say three-sixteenths of an inch. Result: details in full, and sufficiently dense to print, the negative perfectly clean, free from pinholes, comets, spots—in fact, everything was absent that has ever tended to harass and perplex the photographic existence.

Another plate similarly prepared the same evening, and exposed about half a minute after the first for fifteen seconds was only slightly under-exposed. The development was as follows:—We placed the plate, film upwards, in a dish of water when equally moistened we poured over it the following solution:—

Water	1 ounce.
Carbonate of ammonia	3 grains.

to which had been added a few drops of the alcoholic solution

W. P. BOLTON,

Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*, 1879-1885.

—thus rendering unnecessary the use of the nitrate sensitising bath. As the *BRITISH JOURNAL OF PHOTOGRAPHY* was the only paper in which this important communication appeared I append an extract from it. Undoubtedly Sayce and Bolton's

pyrogallie acid, viz., ninety-six grains of the former to one ounce of the latter.

Development commenced at once; but owing to the extreme transparency and thinness of the film, one or two minutes passed before the details were distinctly visible, when a piece of white paper was placed underneath. At this stage the plate was thoroughly washed; afterwards—in order to neutralise the alkali—rinsed with a little very dilute acetic acid; and then sensitised in the ordinary manner, using the following solutions for that purpose:—

No. 1 SOLUTION.

Pyrogallie acid	1½ grain.
Citric acid	1 grain.
Distilled water	1 ounce.

No. 2 SOLUTION.

Nitrate of silver	30 grains.
Distilled water	1 ounce.

Two drachms No. 1 add two or three drops of No. 2.

The negative rapidly acquired density. When sufficiently dense it was washed and fixed with a saturated solution of hyposulphite of soda, then washed thorough and dried. It yielded a good print. A wet collodion plate under the same circumstances would have required about ten seconds. Twenty seconds would probably have sufficed in our case.

Several modifications of the above process have occurred to us, the experiments connected with which we are now following. We purpose making the film more opalescent, and have hopes of accelerating the exposure so as to equal in rapidity that of bromised or wet collodion.

As far as we can judge from our short experience, the process is singularly free from the risks that have hitherto beset dry-plate photography, and the easy manipulation equals, at least, that of the wet process. One dozen stereoscopic plates may be prepared by one person in half-an-hour—exclusive of cleaning the glasses.

We are not in a position to say whether the collodion deteriorates by prolonged keeping. We know that hitherto we have had no loss in sensitiveness; but, of course, it must be kept in the dark. A bottle in a wooden case, such as those sold by us, is very suitable for the purpose. It had better be painted over with black varnish, and covered with yellow or brown paper.

Having regard to the chemical equivalents in the formation of bromide of silver, the weight of the bromide salts and of the trace of silver may be extended at discretion, as also of the crocoylene, but it will be found desirable not to have the collodion too thick.

Excess of bromide produces insensitiveness.

No doubt many experimenters will at once give the subject their attention, and aid us by the publication of their observations.

B. J. SAYCE, W. B. BOLTON.
Liverpool, September 3, 1864.

William Blanchard Bolton was born at York in the year 1848. It was in the month of September, 1864, that the collodion-emulsion process, with which his name, and that of the late Mr. B. J. Sayce were associated, was published in the pages of the BRITISH JOURNAL OF PHOTOGRAPHY, so that, although still, comparatively speaking, a young man at the time of his death, he had been before the photographic world no less than thirty-five years. In the year 1865 his name figures in our "Almanac" as the Honorary Secretary of the Liverpool Amateur Photographic Association.

In the month of January, 1874, Bolton published in the BRITISH JOURNAL OF PHOTOGRAPHY a washed collodion-emulsion process, and for several years considerable commercial success attended the method which owes its origin to him of removing the soluble salts from the emulsion and adding an organifier. This amounted to an almost revolutionary improvement in the

unwashed process of Sayce and Bolton, introduced ten years before; and, looking back, it must appear strange that so obvious an improvement should have escaped notice long.

For many years one of its most valued contributors, Bolton became Editor-in-Chief of this Journal on January 1, 1879, and occupied that position until the end of 1885, when the late

A. J. WILSON.

A former contributor to the BRITISH JOURNAL OF PHOTOGRAPHY and now the well-known financial writer and Editor of "The Investors' Review."

Mr. J. Traill Taylor resumed his occupancy of the chair. During the years 1879-84 Bolton's writings and experiments on the preparation of gelatine emulsion were both valuable and voluminous, and there is no doubt that in the early days of the new process much useful knowledge was gained from what he published in these pages on the subject.

B. J. SAYCE.

Mr. Sayce, at the time of his death, was fifty-eight years of age. It was in this Journal for September 9, 1864, that the brief but lucid paper, entitled "Photography Without a Silver Nitrate Bath," appeared over the signature of B. J. Sayce and W. B. Bolton, from which an extract is reproduced above. The immediate practical outcome of the publication of the paper was to pave the way for the comparative desuetude of bath photography, the introduction of dry collodion plates, and ultimately of gelatine plates, which, between them, have unquestionably been instrumental in carrying photography to the pitch of excellence it now occupies. The experimental work so happily begun was continued by Mr. Sayce during several succeeding years, and many practical ideas and suggestions subsequently emanated from him in connection with the process.

Mr. Sayce was one of the original members of the Liverpool Amateur Photographic Association, in which he took a deep and active interest until the time of his demise. In 1888, when Liverpool was marked for the holding of the first International Photographic Exhibition ever instituted, Mr. Sayce was president of the association, and he also took a large part in the affairs of the association, when under the presidency of Mr. Adolph W. Beer, the first club rooms in St. George's Crescent, were entered upon by the members. For an exhibition of the method of his discovery, Mr. Sayce was awarded a gold medal at the Inventions Exhibition, held in London in 1885, and of this signal honour he was justly proud. Mr. Sayce was one of the most popular members of the Liverpool Association, and was always ready with information and advice to those less skilled than himself in the art.

CHAPTER X.—THOMAS BEDDING.

IN the early eighties, when Bolton conducted the *BRITISH JOURNAL OF PHOTOGRAPHY*, and made it the vehicle for his voluminous writings on gelatine emulsion photography, there is no doubt the paper was widely read for this feature and this feature only. Experimentalists, investigators, and manufacturers vied one with another in giving their results publicity, and thus until about the year 1885, when the commercial manufacture of gelatine plates finally assumed the shape of a

way he knew a very great deal of the practical possibilities of the various types of objectives in common use.

It must be left to some future chronicler—he who will undertake the Centenary Task in the year 1954—to deal in detail with the more recent history of the *JOURNAL*; the facts and occurrences are too near to appear in their proper proportion. But perhaps the present editor, in drawing a very congenial task to a conclusion, may be forgiven if he lightly runs over

Photo by]

THOMAS BEDDING, Editor-in-Chief of the *BRITISH JOURNAL OF PHOTOGRAPHY*.

1895 —

[H. Walter Barnett, Knightsbridge, London.

scientifically regulative enterprise, the pages of the *JOURNAL* were the recognised means of communication between those who were engaged in the daily task of working out some sort of system of plate manufacture.

Upon resuming the chief editorial in 1886, and until his lamented death in 1895, Taylor in the *JOURNAL* gave prominence to the optical side of photography—a subject which was always uppermost in his mind. Taylor's "trial and error" knowledge of a lens was considerable, and in a rough-and-ready

the story of the *JOURNAL* during the last thirteen years—his perhaps, being the only pen quite qualified to do so. It was in the year 1891, after a novitiate of seven years as a contributor, that Thomas Bedding was appointed assistant editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*. In 1895, on the death of Taylor, he was elevated to the position of editor-in-chief. During those thirteen years the power, influence, and prestige of the *JOURNAL* have expanded in a ratio far greater than in any like period of its career. In 1891-1892 the *JOURNAL* was

successful in raising a fund of £700 for the veteran Dr. Maddox, the inventor of the dry plate. Its ungrudging support was extended to the Photographic Society of Great Britain, the Photographic Copyright Union, the Photographers' Benevolent Association, the Convention, and many kindred bodies. It founded the Traill-Taylor Memorial Lectureship in memory of its former editor. The lecture has since been annually delivered by such distinguished men as T. R. Dallmeyer, F.R.A.S., Major-General Waterhouse, Frederic Eugene Ives, Professor H. H. Turner, F.R.S., Professor Silvanus P. Thompson, F.R.S., and Sir W. de W. Abney, F.R.S. Largely owing to the firm and

consistent support of this JOURNAL, the International Crystal Palace Photographic Exhibition of 1898 was a pronounced success. The establishment of the Professional Photographers' Association, a society of 700 members, is also due to the efforts of the JOURNAL and its editor. An enumeration of the minor fields of photographic activity in which the JOURNAL has beneficently exerted need not perhaps be given here; let it suffice to say that for the past dozen years the policy of the JOURNAL has been to support without stint or qualification every movement clearly shown to have for its object the advancement of photography.

Photo by]

F. J. MORTIMER,

[Furie Lew's.

Sub-Editor of the BRITISH JOURNAL OF PHOTOGRAPHY, 1904—
Late Hon. Sec. Southsea Photographic Society.

New Apparatus, &c.

Two New Cameras. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London.

The No. 3 Combination Weno possesses all the latest improvements in film camera construction. The design is new, and comprises features which will appeal to those who wish to use films and plates and have the advantage of focussing the subject full size on a ground glass.

This Weno is so constructed that the film chamber may be removed and a plate adapter placed in its position, transforming the camera from a film to a plate outfit, or vice versa. Films and plates being in the same focal plane, only one focussing scale is required, and by an ingenious arrangement any picture may be focussed on the ground glass while a spool of film is in position.

The camera is fitted with rack and pinion for focussing, rising and falling front, tripod sockets, R.R. lens, and Bausch and Lomb automatic shutter, is Morocco grain leather covered, and has polished mahogany bed and nickel fittings. The entire apparatus is very compact and well finished.

The "Royal" Guinea Magazine Camera is well finished with mahogany body, covered morocco leather, with high-grade achromatic lens, in focussing mount (from 7 ft. to infinity). It is also fitted with three colour screens for isochromatic work, giving an increase of exposure $2\frac{1}{2}$, 5, and 10 times respectively. Shutter is of improved construction, giving various exposures, from 1-100th to 1 second,

as well as time and intermediate speeds. The changing is easy to understand and apparently difficult to put out of order. Two brilliant view finders for upright or oblong pictures are included, and tripod sockets for stand and automatic plate register.

Messrs. Staley have also introduced a new registered stop for use with Unicum shutters, all sizes. This stop will at once appeal to many thousands of users of Unicum shutters. It is instantly adapted by the purchaser, and requires no fitting. It enables the operator to open the shutter for focussing when set at any speed, to

avoiding the necessity of setting the shutter at time before being able to focus. It will fold up on any camera, and can be at once detached from the shutter if desired.

"Platinotype Postcards and Papers," made by the Platinotype Co., 22, Bloomsbury Street, New Oxford Street, London.

The Platinotype postcards, which possess all the good qualities of the Platinotype paper, are put up in the familiar hermetically-sealed tubes, with rotating cutter. Each tube contains eight postcards, with the usual printed matter on the front, and space for communication and sufficient D salts and citric acid to respectively make 10 of developer and 20 oz. of clearing bath. Two masks are included.

The Company have comparatively recently placed some new papers on the market, viz., KK (thick, fine surface), TT (thick rough), (smooth, extra thick), and ZZ (rough, extra thick). The weight of the new papers, taking the AA paper as representing 1, are approximately as follows:—KK and TT, $1\frac{1}{2}$; and YY and ZZ, $2\frac{1}{2}$. They can be supplied sensitised in black or sepia, the two last at a slight extra cost. With the thick papers there is a distinct tendency to give a brighter image, with greater resisting powers against dust and rough usage.

"The Imperial Triple Extension Outfit" and "Panoptic Shutter," made by the Thornton-Pickard Manufacturing Co., Ltd., Alton, Lancs.

The Imperial Triple Extension Outfit puts into the hands of the amateur, and others who do not desire to spend a large sum on the purchase of a complete outfit, a well-constructed camera of new

original design, fitted with every practical movement for general all-round work, snap-shots, copying, enlarging, and telephotography.

The camera has an extension of 22 in. in the half plate size, and closes to 3 in. for use with short-focus lenses.

The outfit includes the camera, with triple swing back, rising, falling, and cross front, triple swing front, triple extension, reversing rack, double rack and pinion, and brass turntable. A Beck symmetrical lens, with Iris diaphragm f-8, is included, and double book-form dark slide, with hinged division, three-fold stand, and Thornton-Pickard time and instantaneous shutter with speed indicator.

The Panoptic shutter is a new between-lens shutter introduced this season to supply the demand for an English-made diaphragmatic shutter combining accuracy and efficiency. It gives exposures with the same precision and reliability as the Thornton-Pickard roller blind shutter. It can be fitted to all lenses with apertures up to f-5.6 in., being thus suitable for lenses from quarter plate to half plate.

The shutter is opened for focussing by means of an independent lever. All working parts are enclosed in an aluminium box, and it works smoothly without vibration. It has pneumatic and lever release, and is set without exposing the plate. The speed indicator is marked to give time and bulb exposures, and exposures of 3, 2, and 1 second, and $\frac{1}{2}$ to 1-100th of a second.

The Ross Focal Plane Camera, sold by Ross, Ltd., Clapham Common, London.

A new and improved pattern of this camera has been placed on the market this season by Messrs. Ross, Ltd. The focal plane shutter has

practically the whole of its working parts now securely and neatly covered in, while the speed can be easily adjusted from the outside. It is arranged for either time or instantaneous exposures of 1-10th to 1-1000th of a second; both being equally certain in action and efficient in result. The shutter works very smoothly without vibration, especially with the slow instantaneous and time exposures, which is a feature that will appeal to those who wish to do indoor portraiture, etc., with the camera.

The body of the camera is collapsible and extremely compact. The woodwork being ebonised and finished with a dull polish, and the body containing the shutter is covered with morocco leather. The extending front, with its rising and falling lens board for vertical and horizontal pictures is supported by very strong metal arms, which are absolutely rigid when the camera is open for use. The front is

thus kept perfectly plane with the sensitive surface of the plate, and absolute definition is obtained with the largest lens aperture. The Ross Patent Homocentric Lens is fitted to this camera, and the definition we have obtained with it at full aperture is beyond re-

proach. The lens usually supplied is of the Series C, working at f-6.3, but one of the Series B, f-5.6, may be had at a slight extra cost. The lens is mounted in a focussing jacket on which the distances from two yards to infinity are accurately engraved.

Roller double dark slides or changing box are supplied with the camera, both being of perfect finish and reliability.

"Aptus" Specialities, made by Sharp and Hitchmough, 101 and 103, Dale Street, Liverpool.

The "Aptus" Repeater Camera, to take stamp-size photos (called "Sticky Backs"), is a well-made instrument of precision. It is made to produce either 12 or 16 photos of different sitters on a half plate, and, by having an extra repeating slide and fittings, to take eight or nine photos on the half plate the same camera will produce the larger pictures. By having further extra slides and fittings, larger or smaller photos may be made at will, i.e., four, six, or any other number on the half plate according to what may be decided upon. The camera is very strongly made, and well finished and highly French polished; is fitted with rack and pinion focussing adjustment, bellows body, rack and pinion to rising front, loose lens panel, extra panel, reversing back for vertical and horizontal pictures, double repeating back, and one single dark slide for any of the following sizes, viz., 4, 6, 8, 9, 12, 16, or 18 photos on the half plate.

For use with these cameras, a special printing frame in three

styles and adapted for taking two sizes of negatives is made, and is a most ingenious piece of apparatus. No. 1 frame is flat, taking a large sheet of bromide paper to make eight dozen to twelve dozen

prints, according to size of pictures. The pressure board of this frame requires to be opened after each exposure to adjust the paper for the next, the printing of eight dozen or twelve dozen taking about fifteen minutes.

No. 2 frame is also flat, of similar construction, but more convenient to work, as the pressure board need not be opened during the printing, and the time taken in printing is only about ten minutes.

No. 3 is a printing machine of very portable construction, measuring 16 in. by 6 in. by $2\frac{1}{2}$ in. The paper is rolled up and wound from one roller to another from the outside. This machine is simple, easy and quick to work. Time for printing about twelve minutes.

The "Aptus" Card and Paper Cutter.—This cutter is well constructed in every detail. The tables are made of hard wood, and fitted with a graduated back gauge. The movable steel blade is curved, giving a drawing cut so essential to smooth work. The efficiency of the cutter is increased by the combination of the curved movable blade and the peculiar construction of its pivotal spring joint, which allows the blade a slight lateral motion, and thus secures perfect contact of the two blades at every point. This gives smooth edges to the card or paper which is cut.

The "Aptus" B.P.U. Camera for 1904 is a well-made magazine camera for twelve quarter plates or twenty-four films in sheaths, with automatic counting indicator registering the number of exposures. It has a high-class achromatic lens, giving fine definition, with open aperture; Iris diaphragms; two brilliant finders for vertical and horizontal work; and is fitted with a new time and instantaneous shutter with patent time arrangement, giving exposures from 1 second to 1-100th. Focussing extension for portraits and near objects is accurately scaled in yards. Twelve sheaths for plates or films is included with each camera. Seal or morocco grain case with stitched handle. The camera is cheap and good.

The "Argus" Reflex Camera. Made by Watson and Sons, 313, High Holborn, London.

This camera is essentially a portable hand camera, and is, we believe, both as regards dimensions and weight, the smallest and lightest of the reflex type. Its dimensions in quarter plate size are 6 in. by $6\frac{1}{2}$ in. by $5\frac{1}{2}$ in., and the weight only $2\frac{1}{2}$ lb. The focal-plane shutter is of a new pattern, giving either time or instantaneous exposures, and by an ingenious mechanical contrivance is so arranged that when time exposures are being made the reflex finder and focussing adjustment are still available. The mirror is silvered on the surface (which is protected by a coating of transparent varnish), and gives an absolutely true reflection; the action of the mirror rising is quite silent. The camera is strongly made, with all metal and wood

fittings finished black, the whole presenting a handsome and unobtrusive appearance. The lens is the Holostigmat Series I. f-6, 6 in. focus, with Iris diaphragm. The double dark slides are fitted with flexible roller shutters, and bound with aluminium.

The camera has rackwork focussing adjustment, and rising

motion to the front, in horizontal and vertical directions, and fitted with socket for attaching to tripod.

The "Velox" Amateur Printer. Sold by J. J. Griffin and Sons, Ltd 20-26, Sardinia Street, Lincoln's Inn Fields, London.

The things that are absolutely necessary in making Velox print are few in number and simple in character. The essentials are light—either daylight or artificial light—developing and fixing solution and water for washing the prints. If artificial light is used, it may vary from a "tallow dip" to an arc light, and no apparatus beyond the simplest form of printing frame is required in making exposures. A convenient apparatus, however, for measuring the distance from the light and for adjusting each negative to the proper angle of exposure to produce the best results is of great assistance. It is with this object in view apparently that the Velox amateur printer has been placed on the market. The illustration sufficiently explains its scope. The apparatus is well made, and nickel finished, and the various adjustments for raising, lowering, or inclining the shelf on which the printing frame is stood during exposure, are very complete. The bottom rod, with the gas burner at one end, and the sliding upright rod holding the printing frame support, at the other, is marked in inches and fractions to ensure identical distance between negative and light for future exposures. Fittings for electric light are also supplied.

The "Professional" P.O.P. is also a new introduction by Messrs. Griffin, and is intended more particularly for professional work. As it is generally admitted in the case of printing-out papers a result somewhat softer than the usual result is necessary for pro-

fessional purposes. Messrs. Griffin claim that the "Professional" P.O.P. has the following qualities, which should specially appeal to the profession: (1) Only Rives finest raw paper is used. (2) Soft delicate prints are produced without harsh contrasts appreciable. (3) An economy is effected in the use of gold in toning to enable the profession to test the claims made for this paper. A full sample sheet will be sent to any professional reader of this journal, free of charge upon request to Sardinia Street.

Lumière Films (Planchon Process). Made by Lumière N.A. Co., Ltd 4, Bloomsbury Street, New Oxford Street, London.

The new orthochromatic series of roll films now issued by this firm are well up to the high standard they have set with their other productions. These films are coated with the well-known Lumière Orthochromatic A Emulsion, and for work where correct colour values are desired are most satisfactory. They are developed, fixed, and printed in the usual manner, and are clean working and of good rapidity. Dianol is the developer specially recommended, and a convenient formula is: Water, 5 oz.; anhydrous soda sulphite, 66 grains; Dianol, 11 grains.

The makers do not advise the use of glycerine as a preventive

curling, but advise rather rolling the dried films round a pencil or piece of tube, film side outwards. If this be done, and the film kept in position by a rubber band for a few hours, the tendency to curl will be found to have disappeared.

The base of Lumière films being of a specially clean and transparent character, enlargements of a perfect nature can be readily made from negatives produced on this film.

The "Challenge" De Luxe Camera. Made by J. Lizars, 101 and 107, Buchanan Street, Glasgow.

The special feature of this fine hand-stand camera are briefly: The lens, shutter, and finder, all close up within the camera, and with focussing screen and hood, combine in one; the universal swing front, which possesses enormous rise, extreme side movement, great extension with perfect rigidity, and can be set back for extreme short focus lenses, and tilted to any degree upwards or downwards;

Independent lens panel rising and falling front; swing back; camera can be instantly opened, and front pulled forward on brass guides, and securely fixed at any position by means of quick acting lever; automatic lock, which securely fixes the front at infinity distance—the position generally used for snap-shot work, and graduated lens scale. The camera is supplied either polished or leather-covered, and the make and finish have all the characteristics of British workmanship.

Half-Plate Roll Film "Carbine" Hand Camera. Made by W. Butcher

and Sons, Camera House, Farringdon Avenue, London, E.C.

This camera is a most practical and compact instrument, folding,

into an astonishingly small space, considering its capacity. It is substantially made in walnut, polished inside, and covered in Morocco-grained leather. It has leather bellows, aluminium base-board, rising and cross front, and double extension. The back of camera is fitted

with removable panel for inserting dark slides, and focussing screen, and has a swing back movement, by means of catches in the side struts. Focussing is by means of ordinary rack and pinion, with scales for both short and long focus lenses. The lens is a Beck rapid symmetrical, with patent detachable flange for using lens in any other camera, and the shutter is automatic between lens, with pneumatic ball and tube; exposures from 1-100 to two seconds. A spirit level is attached to the view finder, reversible for horizontal and vertical, and the finder (brilliant form) is reversible for horizontal and vertical views. Messrs. Butcher have also introduced a new form of dark-room pin, which is a print hanger as well, and should prove a very useful little item in the dark-room.

"Barnet" Specialities. Made by Messrs. Elliott and Sons, Ltd., Barnet, Herts.

The Barnet Orthochromatic Plate. The introduction by Messrs. Elliott of an orthochromatic plate has already called for expressions of approval from this journal. Subsequent experiences with the Barnet "Ortho" Plate have quite convinced us of the correctness of our first impressions as to its quality, and we can only congratulate the firm on this notable production, combining, as it does, colour correctness and high speed. We understand that Messrs. Elliott are in the unfortunate (or fortunate?) position of not being able to keep pace with orders for this plate. Our personal experience also of the Barnet lantern plates, which we have used extensively, is equally satisfactory. The Barnet Roll Film is a celluloid film, evenly coated with a remarkably good emulsion, quick and clean. Density is easily obtained, and there seems to be no tendency to fog; in fact, there appears to be a surprising amount of latitude in exposure, which, combined with its undoubted speed, makes it a very desirable film to handle. Barnet "Lustra Matt." bromide paper has qualities of its own that commend themselves to the bromide worker at sight. We find the claims made for it well substantiated in fact. These are: Good range of tones; beautiful surface; remarkable purity in the whites; luminous rich black shadows, giving a wealth of detail; quick printing, just the right paper for contact work; nothing new to learn in the way of manipulation. A free sample may be had for the asking.

Novelties by Jonathan Fallowfield, 146, Charing Cross Road, London.

A new camera of the popular folding form has been put on the market by this firm at a surprisingly low price. It is a well-made little instrument, with good lens and shutter, and possesses all the necessary qualifications for a snap-shot camera. The dark slides are book-form, with pull out aluminium shutters. Flashlight sachets: These useful and portable little flashlights are likely to have a great vogue. They can be carried about in the pocket ready for immediate use, and can be attached by the ring, which is fixed to each, to any

convenient nail or projection. The hooked string, which is supplied with each box, is fixed in the little tab on the under side, a sharp pull explodes the sachet bon-bon fashion, and a brilliant flash results

with but little smoke or noise. Their utility is extensive and obvious. A price list and samples of photographic buttons and jewellery, and apparatus for producing the same, is also to hand from this firm, from which we glean the knowledge that this phase of photographic

production is steadily on the increase, and judging from many of the chaste and neat designs submitted, we can easily understand the reason. As an exceedingly remunerative side-line, we can commend these photographic buttons, medallion frames, brooches, etc., to professional photographers all over the country.

The "Rajar" Camera and Changer. Made by the Brooks-Watson Daylight Camera Company, Ltd., Great Homer Street, Liverpool.

The ingenuity of the inventor has from time to time been exercised with varied degrees of success in producing clever devices to obtain daylight changing. There has, however, always been some

Loading the Rajar Changer with a sealed case of films in daylight.

serious objections either in the apparatus itself or the material required to be used with it, which has considerably handicapped the user, and greatly limited his photographic efforts.

The "Rajar" system appears, however, in combination with the new "Claron" films, of which we hope to speak more fully and to provide a method of daylight changing which should commend itself to the requirements of every photographer.

The "Rajar" Changer is in dimensions no larger than a dark slide and is similar in appearance. The quarter plate size is only $3\frac{1}{4}$ by $5\frac{1}{2}$ in. by $\frac{1}{8}$ in. It consists of a thin sliding box, closed at the top and

The Rajar Camera, with Changer half drawn in the act of changing a film.

open at the bottom, and just large enough to hold one of the thin cases of films. This is contained by an outer box or case, and the changing is effected by an exceedingly simple movement, which appears to be perfectly reliable, and requires no more effort than pulling out the shutter of a dark slide and shutting it again. The new quarter-plate "Rajar" Folding Pocket Camera has been specially designed for use with the "Rajar" Changer, although double dark slides or any other form of magazine can be used if desired. It can be used as a stand or hand camera, and is a very complete little instrument for all-round work. It is well finished in every particular and embodies all the usual movements.

This enterprising firm, in order to induce users of the "Rajar" Changer to demonstrate its action whenever opportunity arises, offers until further notice, a free packet of "Rajah" films to any "Rajah" worker who will send them on a form, which can be obtained from any dealer or direct, the signatures and addresses of ten persons to whom the Changer has been demonstrated by the worker.

New Productions by the Bayer Company, Ltd., 20, Booth Street, Mosley Street, Manchester.

Five new printing papers of high quality are introduced this season by the Bayer Co. They are St. Luke's, Pan, and Tula gaslight papers; Bayer Bromide Paper; and Aristo Paper. The three former are made with several kinds of surface, the St. Luke's being a remarkably quick printing paper. In direct contact printing only a few seconds' exposure is necessary. The subsequent developing and fixing does not necessarily require to be conducted in a dark room with ruby light. Prints can also be made by gas, petroleum, or candle light. St. Luke's is specially adapted for the production of black tones, but brown or brown black tones may also be obtained by varying the length of exposure and by altering the strength of the developer.

Pan paper is not so rapid, but unlimited keeping qualities are claimed for it, and it yields a great variety of tones from yellow, through orange and brown, to black, according to the exposure and developer employed. The special concentrated Edinol developer is recommended for use with this paper, and instructions are given for securing any particular tone required. Pan has the further advantage of being capable of treatment in the gold toning bath, with the usual characteristic P.O.P. results.

Tula paper is a somewhat slower gaslight paper, and is particularly adapted for the production of pure black tones. Tula is the only developing paper on the market that we are aware of that will bear treatment with hot water, or which can be dried by heat. It is therefore specially adapted for use during the summer season and in

tropics. Its durability is unlimited, but its manipulation is no difficult than any other gaslight paper. The bromide paper is a remarkably fine production, giving prints of excellent colour with remarkable ease in the special Edinol developer recommended in the instructions given with each packet. The paper is one of the oldest gelatine printing-out papers of the keeping qualities. It gives prints of great beauty, prints rapidly, tones readily. It lies perfectly flat in the baths, and gives very fine results and fine shadows. It is especially suitable for printing from weak negatives. Either matt or highly-glazed surfaces can be obtained.

Century Cameras. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C. Particulars of novelties connected with these new cameras are to be published. We hope to report on them in a future issue. In the meantime, readers should secure an illustrated catalogue from the above address.

Zimmermann's Focal Plane Cameras. Sold by Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London. A new series of focal plane cameras are supplied at prices so moderate as to bring this type of shutter within the reach of all. Model B, which we illustrate, is of the approved folding pattern. The front is simply pulled out by means of the thumb grips until the struts snap into position; the pointer on the lens is set to the approximate distance of the desired view. The rising front, which is a revolving board, may be used either in a vertical or horizontal position.

The shutter gives exposures from 1-25th to 1-800th of a second; the adjustment of the width of the slit being very simply made with the sliding screen thrown back. Model A is a more elaborate camera in many ways, and is more expensive. The exposures given by the shutter are 1-25th to 1-2000th. Model C has all the good qualities of the other two cameras, but falling base-board and bellows extension, and appears to be a more reliable instrument. A descriptive booklet of the cameras can be obtained from the above address.

"Roto" Roll Film. Made by the Rotary Photographic Company, Ltd., 14, New Union Street, Moorfields, London. This new production of the Rotary Company bears the same stamp of "goodness" that characterises all their goods. Each spool of film is sold in a well-made tin case to ensure its keeping qualities, and development is not proceeded with immediately after exposure, the film should be returned to this case until it can be dealt with in a dark room. This feature will specially appeal to tourists as a safeguard to its keeping qualities under trying atmospheric conditions. The film is of high quality as regards speed and cleanness of work, and is coated on a thoroughly seasoned transparent celluloid, consequently the chances of any action of the celluloid on the emulsion is reduced to a minimum. Another advantage due to the celluloid being well seasoned before it is coated is that it may be

cut into short lengths and developed in an ordinary dry plate developing dish, for as soon as the emulsion is wetted with the developer it lies perfectly flat, and is therefore easily manipulated.

The coating of emulsion is perfectly even throughout, and there is no tendency to frill or peel.

Metol hydroquinone or pyro-soda are the two developers recommended for these films. Good formulae for each are given with each film.

"Sanbride" Picture Postcards. Made by Hood and Co., Ltd., St. Bride Works, Middlesbrough.

A selection of postcards is to hand from this firm, which amply demonstrates the advances that have been made in picture postcard production during the past year or two. Messrs. Hood are specially equipped to provide at short notice and small cost any number of picture postcards from customer's own photographs, the prices quoted for the blocks for printing in half tone being very moderate.

New Mounts. Made by the Crown Photographic Manufactory, Rotherham.

A new series of mounts issued by this firm display a great deal of taste in selection of graduated tints and various shaped openings and plate masks. For professional work they are as good as anything of the sort we have seen. They are, moreover, inexpensive. Samples and price lists will be sent on application.

Patent News.

The following applications for patents were made between May 24 and May 28, 1904:—

Dark Slides.—No. 11,993. "Improvements in and relating to dark slides." Complete specification. Max Hofmann and Georg Schneider.

Shutters.—No. 12,003. "Improvements in or relating to focal plane or other roller blind shutters for photographic purposes." Arthur Lewis Adams.

Dark Slides.—No. 12,038. "Improvements in and connected with photographic dark slides." William Holden and James Schofield.

Materials.—No. 12,125. "Improvements in photographic materials." Alfred William Southey.

WITH June commences the tourist and excursion season of the London, Brighton, and South Coast Railway Company, and in their programme are announced cheap week-end tickets over the wide and interesting region to which the line gives access. The peripatetic photographer should make full use of the facilities offered.

MESSRS. R & J. BECK have lately introduced a new method of accurate shutter speed-testing. They say: "Our attention has been drawn to the failures of instantaneous photography due to the uncertainty of shutters. Many shutters vary, due to time. In others, the speeds originally marked do not correctly indicate the true exposures, and we believe that it would be really a service to the public if they knew what exposures their shutters were actually giving." They have consequently devised a scheme by which, at a nominal charge, they will test the speeds of any photographic shutter which is brought to their Cornhill shop, and if sent by post will do the same at a slightly increased charge, though in this case if the camera has to be sent as well as the shutter it must be carriage paid. It is evident to those who are familiar with instantaneous photography that the speed of one's shutter is comparatively of little importance, provided it is accurately known. The firm supplies a card with a date upon it showing the time at which the shutter is tested, and give no further guarantee for the speeds, as it is evident that in certain classes of shutters, especially those with pneumatic brakes, if they are not carefully kept free from dust, they will vary from time to time. Obviously, for workers with exposure meters, a correct knowledge of shutter speeds is essential, else the speed dial on the meter is of little value.

News and Notes.

THE first instalment of the *BRITISH JOURNAL* "Encyclopædia of Photography" will appear in next week's issue. Readers of the *JOURNAL*, who desire to possess a reliable compendium of photographic information, will do well to file all future numbers. It will be the aim of the compilers of the "B.J. Encyclopædia" to present in brief and readable form a complete guide to photography and all its processes. The best authorities will in all cases be consulted, and much original matter will be contributed by experts.

LONDON and Provincial Photographic Association.—At the meeting on June 16 Mr. R. Child Bayley will give a lantern lecture on "The Alhambra and Spain."

THE subjects dealt with in "The Photo Miniature" seem to be inexhaustible. No. 61, "Combination Printing," should prove invaluable to workers in every branch of photography.

ROYAL Photographic Society.—An ordinary meeting will be held at 66, Russell Square, W.C., on Tuesday, June 14, at 8 p.m. "A New Principle in Photographic Lens Construction," by Conrad Beck.

"THE CAMERA" is the title of a small booklet published by Messrs. Raines and Co., of the Photo Works, Ealing. It contains several useful articles on photographic matters, and is a praiseworthy little production.

On June 10, 1854, the Crystal Palace, after being transferred from Hyde Park at the close of the Great Exhibition of 1851 to Sydenham, was opened by the late Queen Victoria. To-day, therefore, the popular Palace also celebrates its jubilee.

SIR WILLIAM HUGGINS (president of the Royal Society), Prof. H. H. Turner (president of the Royal Astronomical Society), Sir Robert Ball, Sir David Gill (Cape Astronomer), Sir William Abney, and other gentlemen made the annual inspection of Greenwich Observatory on Saturday last.

MESSRS. HOUGHTONS LTD. have sent us a copy of their clearance sale list of odd and surplus stock, which comprises hand and stand cameras of all classes, together with a large variety of lenses, camera cases, shutters, etc. A copy will be sent to any reader on receipt of a postcard to 88 and 89, High Holborn, London, W.C.

THE first part of "The Book of Photography," published by Cassell and Co., Limited, is to hand. It is edited by Paul N. Hasluck, and promises to be a most useful addition to the literature of photography. The contents are divided into Practical Photography, Theoretic Photography, and Applied Photography, and the work will be completed in about twelve monthly parts.

A NEW handbook on the Ilford plates has reached us from the famous Ilford firm. It contains, in addition to much useful information concerning the manipulation of Ilford plates themselves, much that a photographer ought to know, and is generally a most reliable little guide to the production of a good negative. A copy can be obtained from any dealer free, or from Ilford, Limited, Ilford, London, E.

THE forty-ninth Exhibition of the Royal Photographic Society will open at the New Gallery, Regent Street, London, on September 22, and close on October 29. There will be five sections: (1) Pictorial photographs, invitation; (2) pictorial photographs, competitive; (3) scientific and technical photography and its application to processes of reproduction; (4) general professional photographs; (5) photographic apparatus and material. There will be no charge for space in Section 2 and Section 3. The latest date for entries will be September 10.

WITH the thicker varieties of platinotype paper just introduced by the Platinotype Co., mounting can be dispensed with, if paper larger than the negative to be printed from is employed, and the latter masked so as to print with a clear broad margin. This system is very extensively used by professional photographers in the United States, who supplement it by impressing a plate-mark, and printing in various border tints. A combination of the two gives much the appearance of a rich engraving on a laid-down india tint, certainly pleasing to the eye, whatever the ethics on the question may be.

THE proprietors of the "Graphic" announce another Amateur Photographic Competition for this year. Fifty pounds in cash prizes are offered, and the last day for receiving prints is Nov. 1. The

prize photographs will be published in the "Graphic," together with any others which the judges think worthy of special mention. A fee of one guinea will be paid for each photograph reproduced, with the exception of the Prize Photographs. At the last competition a large number of photographs were selected by the judges for publication and special mention, in addition to the prize photographs.

THE Newbury Photographic Exhibition, which is to be held from September 20 to 28, is fortunate in having secured the special patronage of H.R.H. the Princess Christian, whose interest in the art is well known. The exhibition will be held in the Town Hall and Municipal Buildings, and will be on a very large scale. Indeed it will be undoubtedly the largest photographic exhibition ever held in the Royal counties, if not in the south of England. A feature of the exhibition is that valuable cash prizes amounting to over £1,000 will be given, and ten of the classes are open. The schedule of the exhibition should be obtained, as several novelties are included, and can be obtained from E. J. Forster, Guildhall Club, Newbury.

MESSRS. A. E. STALEY and Co. have advised us that they have taken over the entire products of the factory of Dr. Krebs, of Oberbach a/m., and will in future sell all his productions under the name of "Geka" productions. These goods have formerly been sold under the registered trade mark of "Axe Brand," of which Messrs. Fuerst Brothers are the proprietors, the trade mark "Axe Brand" being their property, but in future all the original productions of Dr. Krebs, which were formerly sold under the description of "Axe Brand," will be procurable only through Messrs. Staley, who are now preparing two floors in their premises for the reception of these, and as soon as the necessary catalogues are ready of the various developments, toning, fixing, daylight developing, and other solutions will commence advertising the same.

"THE Year Book of Photography" is to hand, and does credit to the Editor of the "Photographic News." Section I is devoted to "Helpful Articles by Practical Photographers"; Section II is "Photographers' Gazetteer," containing a fund of information about "Where to go," "Where to stay," and "What to photograph"; Section III comprises "Notes and Queries," being a series of useful information, put together in a bright and pithy fashion. Section IV consists of Tables and Formulæ compiled by E. J. Wall, F.R.P., which is a complete reference book in itself, and Section V is a review of novelties of the year in materials and apparatus. The book is embellished throughout with excellent half-tone reproductions, and as a useful volume of reference should be on the book-shelf of every photographer.

ON Thursday last the Thames Steamboat Company, Ltd., started a new epoch in its career, and a fleet of newly-decorated altogether desirable paddle boats churned the murky waters of the Father Thames between Westminster and Greenwich. Last year Londoners were deprived of a steamboat service on the Thames, but as there were hardly more than three days during the winter summer upon which it would have been possible to sail on the river without catching cold, the deprivation was one that can scarcely have been severely felt. From the present summer one may well hope for better things, even though the "leafy month" has come in with an air of determined melancholy. Rain or shine, however, there are to be steamers on our river henceforth, and we can hardly draw the attention of our readers to the new service of boats, where will more charming snapshots of river scenery be obtained than in the "Pool of London," and who knows but what a humble temptation invested in a trip down the river with a camera may result in a Salon triumph or even a R.P.S. medal?

THE Photographic Salon, 1904.—The prospectus of the Photographic Salon is to hand. The exhibition, in spite of rumours to the contrary, will again be held in the Dudley Gallery, Egyptian Hall, Piccadilly. The receiving day is Monday, September 5, from 10 a.m. to 6 p.m., on which day all pictures for exhibition must be delivered at the gallery, either personally or through an agent. The exhibition remains open from September 16 to November 1, and the conditions of entry are much the same as in previous years. Special conditions applying to American exhibitors only are introduced this year. The work of such exhibitors must be submitted to a Selection Committee sitting in New York, and composed exclusively of American members of the Linked Ring. The pictures approved by the American Selection Committee will be accepted for hanging

t passing the London jury. We have a limited number of forms at our disposal, which we will be pleased to send to exhibitors on receipt of stamped addressed envelope.

Selborne Society.—The annual meeting and conversazione of the Society, the object of which is to promote the study of natural history, were held last week in the theatre and halls at the offices of the Civil Service Commission, Burlington Gardens. The President, Lord Avebury, delivered his address in the theatre to a large audience, and in the course of his remarks said that we were beginning to realise the importance of science in education, and that a step forward had been taken by the introduction of nature study into our schools. The Selborne Society had thrown itself heart and soul into the work of forwarding the nature study movement, and last year took a very prominent part in organising the Counties Nature Study Exhibition. The promoters of this undertaking were very successful in their endeavour to show that nature study is not a superficial thing, but that it is a real and substantial work on living things by pupils themselves was the object of nature study. They still heard that nature study was in some degree superficial. That it was elementary he agreed, but it was not at least or not to be, superficial. It was elementary, of course, as science, but not as education; or, if elementary, it was in the sense that it was a beginning. Nature study was good for the mind and for the body.

A reproduction of a photograph of a rifle-shot is interesting inasmuch as the said shot was travelling at the rate of 20,000 ft. per second. The exposure was one-millionth part of a second,

made by means of the electric spark. The plate used was Schussner's Special Rapid Observatory plate, particulars of which may be obtained from Thomas Christy and Co., Old Swan Lane, Thames Street, London, E.C.

International Catalogue of Scientific Literature.—The International Council, which is the governing body of the International Catalogue of Scientific Literature, held its first general meeting on Monday and Tuesday of last week, at the rooms of the Royal Society, the meeting of the International Association of Academies. The conference was attended by representatives of Austria, Denmark, Germany, Great Britain, Greece, Holland, Hungary, India, New South Wales, Norway, and Russia. The catalogue dates from January, 1901. Its inception is due to the Royal Society of London, and it is the outcome of negotiations extending over about ten years during which time no fewer than three international conferences were held in London to discuss and settle preliminaries. The object is to provide complete classified subject catalogues of current scientific literature in a form to enable workers to ascertain the state of progress in all branches of science. A striking picture of the scientific activity of the various countries concerned in the work is afforded by the following table in the report showing the number of slips or equal entries received at the central bureau:—Austria, 6,379; Belgium, 584; Canada, 537; Denmark, 1,722; Finland, 707; France, 1,445; Germany, 146,552; Holland, 6,557; Hungary, 1,745; India, 2,231; Italy, 13,473; Japan, 2,208; New South Wales, 1,016; Norway, 327; Poland, 1,303; Russia, 3,492; Sweden, 21,071; South Africa, 645; South Australia, 130; Sweden,

1,457; Switzerland, 1,932; United Kingdom, 43,484; United States, 37,688; Victoria, Australia, 1,445; Western Australia, 16—total, 243,503. It will be seen that Germany supplies about half the material for the catalogue; France, the United Kingdom, and the United States come next in order, but no one of these countries supplies more than one-eighth of the entries. The publication of the 17 volumes of the first annual issue was not completed until February, 1904, owing to various causes which delayed the organisation. Nine of the volumes of the second annual issue have already been distributed. It is anticipated that the completion of the first five annual issues will not be delayed more than two or three months beyond April, 1906, the date originally contemplated. The volumes vary in price, according to their size, from 10s. to 39s. At present their cost is undeniably high. As soon as sales to the public become considerable, however, it will undoubtedly be possible to cheapen the catalogue. The value of such a work can become known only gradually, but it is to be hoped that all concerned in the progress of science will assist in promoting the enterprise by freely subscribing to its support. The various volumes must ere long prove to be indispensable to all serious students of scientific progress.

FORTHCOMING EXHIBITIONS.

June 12-24.—First International Salon in The Hague. Sekretariat. Haag, Conrad Kade 63, The Hague, Netherlands.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Secretary, W. Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. M. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. sec., H. C. Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills. Leeds.

FORTHCOMING COMPETITIONS.

June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

June 30.—Kodak. £1,000 in cash prizes for pictures taken on Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June	Name of Society.	Subject.
13	Southampton Camera Club	Printing Processes. Debate.
14	Nelson Photographic Society	Members' Print Evening.
15	North Middlesex Photo. Soc.	Carbon Printing. Mr. H. G. Seshorne.
15	Everton Camera Club	Platinum Toning on P.O.P. Demonstration. Mr. C. B. Stonehouse.
16	Lon. and Prov. Photo. Assoc.	Lantern Night.
16	The Optical Society	Stereoscopic Living Pictures. Demonstrated. Mr. Theodore Brown.
16	Watford Camera Club	Competition—"A Hertfordshire Lane Scene."

Several reports of meetings are held over until next week.

Correspondence.

- * * Correspondents should never write on both sides of the paper; notice is taken of communications unless the names and addresses of the writers are given.
 * * We do not undertake responsibility for the opinions expressed by correspondents.

Several interesting communications have been held over this owing to the extreme pressure on our space. They will appear in next week's issue.

Answers to Correspondents

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
 * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
 * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
 * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the fee.

We must crave the indulgence of our numerous correspondents to wait and refer them to our next issue for replies to their queries.

COMMERCIAL AND LEGAL INTELLIGENCE, STUDIO GOSSIP, AMERICAN NOTES AND NEWS have also been held over this issue through lack of space.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, South Africa, India, Japan, etc.
Half Year	5	5	Germany, Russia, Poland, Spain, Italy, Egypt, India, Japan, &c. One Year ... 13s.
Quarter Year	2	9	

It may also be obtained from all Booksellers, Photographic Dealers, and Railway Bookstalls.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 2302. VOL. LI. FRIDAY, JUNE 17, 1904. PRICE TWOPENCE.

THE BRITISH JOURNAL JUBILEE NUMBER.

This Special Jubilee Number of THE BRITISH JOURNAL OF PHOTOGRAPHY, which we published on Friday, June 10, met, we are pleased to say, with a most cordial and durable reception at the hands of the photographic public—indeed, the success achieved was so striking and instantaneous as to cause even ourselves, who had anticipated the Special Number would secure a wide degree of appreciation, the liveliest feelings of gratification and assurance at the chorus of commendatory approval meted out to the issue.

Several extra thousands of the Special Jubilee Number have been printed, and they are selling rapidly at the ordinary price of twopence per copy, or by post twopence-halfpenny. The number consists of a total of 132 pages, and forms the largest ordinary issue of any photographic journal ever published in the United Kingdom. The contents include thirty special articles by the foremost photographic authorities of the time; a history of THE BRITISH JOURNAL OF PHOTOGRAPHY since its foundation; and about twenty original portraits of celebrities connected with photography; thus forming a unique and most interesting souvenir of the Jubilee of the oldest photographic journal in the world.

This souvenir number of the JOURNAL is in such great demand, and is shortly likely to be scarce, that readers at home and abroad who have not yet secured a copy are advised to do so without delay.

EX CATHEDRA.

A New Method of Making Platinocyanides. The tedious method ordinarily adopted in the making of platinocyanides is well known, but in the recent "Comptes Rendus" of the Paris Academy of Science M. André Brochet describes a method he has discovered which may facilitate the production of this salt, which holds the field for brilliancy of image under the influence of Röntgen rays. He finds that it behaves as iron and cobalt towards an alternating electric current, and dissolves very easily in cyanides, a chemical action of considerable interest in view of the fact that platinum is such a refractory metal with regard to chemical agents.

* * *

Lightning and Studios. It has often been a source of surprise that so few instances have been recorded of damage to photographic studios through being struck by lightning, seeing that, as a rule, they occupy the highest part of a building. It should, however, be remembered that they are usually surrounded by chimneys, which, in the case of a thunderstorm, would be the most likely points of attraction for the electric discharge. In the event of the erection of a studio where, however, a lightning conductor is decided to be fixed, some remarks recently made by Sir Oliver Lodge at a meeting of the Institute of Architects, will be found useful. He had some models on the table representing the effect of an electrically charged cloud which was made to discharge through copper, iron, and wet string. He held the opinion that iron was quite as efficient as copper—and of course much cheaper—and more, seeing that copper was more likely than iron to set up "side-flash," which, in buildings furnished with lightning conductors, had been the origin of most lightning disasters.

* * *

Suggestion for a New Subject for Photography. In these days of the post-card and of illustrations for magazines, every hint as to a possible new subject is acceptable. We make our readers a present of one that would be decidedly novel. There is a devoted band of a dozen young men, who, under the rigid surveillance of the Chief Chemist of the American Agricultural Department, have been since the beginning of the year, to the end of May, literally living on poisoned, or, at any rate, adulterated food, in order to ascertain the actual result upon the human economy of the ingestion of a variety of the substances commonly used to adulterate or preserve from decomposition the food supplied to the nation. Everything they ate has been more or less soaked with salicylic, sulphuric, or benzoic acids, such substances as are employed by domestic and foreign packers in preparing meats, butter, and other products for shipment. The

results of the trials will not be made known until a formal report is presented to Congress. Meantime, the "Poison Squad" is disbanded. What a taking title!—"the Poison Squad"! If these young men know their business they will not permit themselves to be photographed except upon terms—"cash down" and "no spec."

* * *

Self-lighting Gas Burners.

Many of our readers are acquainted with the property of spongy platinum of becoming heated to redness when a stream of hydrogen impinges upon it, and thus causes the ignition of the gas, the well-known Döbereiner's Lamp which was re-introduced in a portable form about a quarter of a century or more ago being an example of a practical use of this fact of theoretical interest. In this instrument there was an arrangement for producing hydrogen at a moment's notice and so obtaining a light, but as the days of the phosphorus match had long since arrived, the only *raison d'être* of this lamp was as a chemical curiosity. Lately, however, the principle has been applied to the fusion of coal gas by finely divided platinum, and a self-lighting Bunsen burner has been introduced which should become popular. A bye-pass connects with a bundle of fine platinum filaments attached to a small bracket at the open end of the burner, and when the gas is turned on it becomes alight through the action of the platinum, the flame being directed by a movable hood in the proper direction to light the mixed gas issuing from the main orifice. The idea is excellent, and the apparatus is said to work efficiently, at least at the beginning of its being put into use. The question is, "Will the apparatus prove to be durable, either as to its existence or its function?" The delicate bundles of platinum used to be very easily put out of order. If it do prove a success, one would imagine that it will not long be confined to the Bunsen burner. It would be a great boon to the user of gas-fires, which are to be found in almost every house in the country, and whose main drawback is the need for a match to be struck to set them going, and the want of a fireplace to throw that match, cigarette ends, or other rubbish for which the open fireplace is so useful a receptacle.

* * *

The Supply of Radium.

"Radium, radium everywhere, but not a gramme to buy," we might, to parody part of a well-known verse, say with perfect truth. Not a daily paper can one take up, and scarcely a magazine, but we are almost certain to read some wonderful tale about this marvellous element, with its perpetual store of heat and continuous emission of radiant energy without sensible loss of weight or apparent change of form; yet the supply is so limited that half a million pounds a pound has been given as an approximate estimate of its market price. We know many photographers desirous of experimenting photographically with it, but so small is the quantity in the whole world they cannot get hold of any to experiment with. It is reported that M. Curie, its discoverer, was once asked what would be the result if a kilogramme of it were stored in a room. "Certain death to any one entering the room," was the reply he is said to have made. A kilogramme! We doubt very much if a single one of our readers has ever seen in one parcel a single gramme of it. All the while we are told of its existence almost everywhere, but, unfortunately, as the Bath people discovered to their chagrin, not in paying quantity. The latest announcement as to a new source of radium is to be found in a newspaper paragraph which states that a new survey of Salisbury Plain is probable on account of the recent appearance of a new lake covering the roadway from the meeting of the Amesbury and Old Marlborough Road to the brow of the descent into Bulford Camp. The

paragraph in question concludes thus: "Divers have been sent for to examine the bottom of the lake, which is supposed to resemble blancmange, and which is thought to contain radium to a large extent together with the wreckage of motor-cars!"

* * *

The Greenwich Visitation.

This annual event took place about fortnight ago, and a detailed account published in most of the science periodicals. We have less than usual of matter possessing photographic interest, the chief reference to which has regard to stellar photography and a new stellar map of all stars between the fifth and ninth magnitude within 26 deg. of the North Pole, all the stars visible over 13,270 being recorded. An idea of the number of negatives taken will be formed when it is known that five observations of each star are required. Ten years was the original estimate made of the time required to obtain all these negatives, but the work has been so well and quickly done that it is now anticipated that this catalogue of reference stars will be finished by the end of next year. Photographers have often been warned of the desirability, when taking a lens to pieces for the purpose of occasional cleaning, of being careful not to screw the lenses up too tight when putting the components together again; a concrete example of the need for this care was shown at Greenwich. It was found last year that certain observations were not in accordance with a standard table of reference, and an investigation into the cause of the error was made, with the result of the discovery that one of the lenses was screwed up too tight, and, further, that it also had a slight tilt. When the faults were recognised and remedied the discordance referred to almost entirely disappeared. A better example could not be found of the necessity for that centring of the lenses which some photographers are inclined to look upon as a sort of tale invented by opticians to excuse the high prices of their objectives. But when it is considered that some modern objectives consist of eight individual lenses, each of which has to be accurately centred, some conception may be formed of the amount of the detail work of the mere putting together of the lenses, after the labour of grinding has been performed, in such a way that they have a common central axis.

* * *

Our Open Spaces.

It has often been pointed out that Londoners know little of the best spots which are to be found in their very midst, and fear that photographers who make great efforts to find out subjects for their cameras far away from the Metropolis are among the ignorant ones. Some of the parks and open spaces offer most charming pictures, at all times of the year, especially before the sun has had time to darken the foliage. Hampstead Heath is still unrivalled as being the most rustic spot near London; it has been the haunt of poets and painters always, and it does not lose its charm. In the South of London perhaps Tooting and Streatham Commons offer the best opportunities for photographic work, but they do not equal Hampstead's variety and scenery. Nor should Hyde Park and Kensington Gardens be neglected, and although they cannot boast of rural characteristics, we can at least see the gay side of life in the form of well-dressed human and splendid equipages. Kensington has always been the haunt of fashion, and a century ago its gardens called forth an inflated eulogy in the "Times," which we now presently quote. The chief journal does not indulge in such grandiloquent language now, nor does it descend to the puerility of a pun, as it often did a hundred years ago. Here is the extract, dated May 21, 1804: "Yesterday

the Metropolis poured forth its myriads in all directions, to enjoy the pleasures of rural excursions. The art of fashion in Kensington Gardens presented an uncommon crowd of beauty and *ton*. We have rarely witnessed a scene so replete with the fascinating characteristics of our country—beauty and elegance. Amongst a crowd of admirers we observed the Turkish Ambassador and his secretary, who appeared to anticipate, in the contemplation of British charms, the promised paradise of Mahomet. "Good old times! Good old 'Times,'" were the Kensington ladies could thus excite the rapture of the newspaper reporter. And yet we may suppose that the hand-camera been possible then it would have recorded nothing more extraordinary than anything we see to-day. The fashions would have been a little different, but the human beings would be much the same they are now. A hundred years hence those who look back will have the advantage of criticising the various changes of fashion as shown by photographs, and for the neglect of posterity pictures of current times should not be neglected. Our open spaces afford unique advantages for the taking of such photographs.

Patents and Trade Marks.

The recently issued Annual Report of the Patents Office, or, more exactly, of the Comptroller-General of Patents, Designs, and Trade Marks, for 1903, affords some interesting reading, and records certain improvements in the working of the Patents Office. That our system of patents is capable of vast improvement needs no discussion to prove. Still, it is better than it was; it is improving, and promises to improve. When Section 1 of the Patents Act of 1902 comes into operation, the date having been fixed by the Board of Trade, every patent application reaching the complete stage will have to be examined for purpose of ascertaining whether, in whole or part, it has been forestalled during the last fifty years by another patent excluding provisional ones that have not been followed by a complete specification. For this purpose the role of the patents involved are being re-arranged for easier reference. Over half a million are involved, and two-thirds are already finished. The abridgments and drawings are to be mounted on cards, and the specifications themselves attached. Last year 28,832 applications were received, which works out to a daily average of about twenty-two. Ninety additional examiners are to be eventually appointed, which would give every application the average possibility of over one day's examination for novelty being made. Of the whole applications of 1903, about 2 per cent. made by women inventors, 3,466 came from the United States, 980 from France, while 2,781 were made in Germany. As shown by the great "Tabloid" Bill, the law with regard to trade marks is capable of amendment, and a new Bill for the purpose has been laid before Parliament, and read a first time. It promises to be largely disputed in parts, but it is to be hoped that the provisions for simplifying the rules confirming existing rights, and reducing the present highly technical limitations may be passed and become really operative. Many persons hold the view that Government monopolies held for the benefit of the public—such as Post Office and Patents, etc.—ought to be worked entirely in the interest of the public, and not made a source of profit. But the former brings in annual millions, and even the latter with its modest quarter of a million pounds of receipts shows a profit of almost exactly one-half of this sum. If that amount were devoted to the purpose of improving the certainty of patents once granted it would be well disposed of; but then there would be fewer Patent law suits, and lower fees and costs for the lawyers.

A School of Art Closed.

Professor Herkomer's School of Art, which he established at Bushey some twenty-one years ago, is about to be closed. The reason for this, so it is said, is that the students, male and female, gave less attention to their work in the studio and expended more time in flirting than was conducive to the gaining of proficiency in drawing and painting. It is quite possible that young people in well-to-do circumstances should sometimes prefer the study of nature in the open in couples, in the picturesque districts of Hertfordshire to the mere drudgery of the studio. Be that as it may, the school is to be closed. Professor Herkomer, it is tolerably well known, is no great friend and admirer of photography. Some ten years ago, in one of his lectures, he denounced photogravure as "a very evil thing." But not very long afterwards—in 1894—he, with Mr. Cox, patented a mechanical method of producing engraved plates, and a syndicate was formed to work the process commercially. The process was demonstrated at the Fine Art Society's rooms in the early part of 1896 before the art representatives of the lay Press. The critiques were quite unanimous as to the virtues of the new process, and it was suggested by the latter that it would eventually supersede the "evil thing," photogravure, as in this process the artist himself's touch would be in evidence in the work. However, photogravure is still flourishing, and we have heard nothing of the "New Art," as it was then called, of late years. The method of working Herkomer's and Cox's process may be interesting to our readers, and it is, briefly, this: The artist is supplied with a silvered copper plate, and on this he paints his picture in oil paint, the paint being composed of a slow drying oil mixed with a black pigment. The shadows of the picture were to be represented in the painting by thick layers of colour, and half-tones by thinner, and so on. The plate was then handed to the process worker, who dusted the surface over with powdered bitumen, mixed with a bronze powder to form a grain. The excess is then dusted off and the plate put aside for a few days for the paint to dry or harden. From this an electrotype is taken, and this forms the printing plate, after it has been re-touched by a skilled engraver. It will be noted here that this process is somewhat akin to the Waterhouse method of photographic engraving, except that in the "New Art" oil paint takes the place of the moist gelatine film, produced photographically by the carbon process. In the Waterhouse process a carbon print is produced on a silvered copper plate, and while it is still moist it is dusted over with a gritty matter, which sinks into the soft gelatine in proportion to its thickness. When the picture is dry the gritty particles are removed and an electrotype made of it. This electrotype is then printed from after the ordinary manner of copper-plate printing. The Waterhouse process has now been superseded by the photogravure system, in which the image is etched through a carbon print developed on the copper plate, upon which a dust grain has been laid. When the "New Art" was first published we made some comments upon it (see page 98 of our volume for 1896), and at the same time expressed great doubts as to whether it would, as some thought, supersede what Professor Herkomer decried as the "evil thing"—photogravure. The opinion we then expressed, it will be seen, has been quite justified.

The Ilford £750 Competition.—In awarding the prizes in this competition, we understand that Ilford, Limited, will avail themselves of the independent help of eminent artistic and photographic experts, whose names will be announced shortly before the close of the competition.

COPYRIGHT INFRINGEMENTS FROM A BUSINESS POINT OF VIEW.

NOTWITHSTANDING that so much has, from time to time, appeared in these pages on the matter of copyright laws as it affects photographers, there seems to be no falling-off in the number of queries we are continually being asked to reply to through the "Answers to Correspondents" column. Many of the subjects have been duly dealt with in the editorial columns many times, and some even quite recently; yet the queries continue to come, not a few of which, in effect, have often been replied to but a week or two before. Why this should be the case it is a little difficult to conceive, unless it be that readers take but little notice of the subject until they find themselves personally interested in it through some real—or imaginary—wrong done them. Then they write to the Editor for his advice in the matter instead of looking up what has already been said. Within the last three months we had two articles on certain misconceptions that some photographers appear to labour under with regard to their supposed rights under the Copyright Act (see pp. 248 and 308 *ante*). Since they have appeared we have had quite a number of queries that were fully answered in those articles.

In the current issue we reply to two correspondents which we refer to here as showing the lack of knowledge they—as well as some others—labour under. One says that he photographed a professional man, registered the copyright, and gave him a dozen copies for the sitting. The sitter, he says, afterwards purchased a dozen copies, and our correspondent asks: "Does that purchase destroy my right to the possession of the negative and the copyright? Also has he (the sitter) the option of giving the right to reproduce?" Of course, the copyright still remains the property of the photographer, and the sitter has no right to give permission for the reproduction of the picture. We call particular attention to this query because it may be assumed that, according to the idea of the writer, the negative is the property of the sitter if there is no copyright in the picture. We know that in some small country towns the sitter sometimes claims the negative, and, by threats of legal proceedings—and "bluff"—occasionally obtains it. The query just quoted somewhat illustrates this, as here the photographer does not seem to be aware that, whether the picture is copyright or not, the negative is his property, and that there have been several decisions given on the point both in county courts and also in the high courts to that effect. The copyright in a portrait that the photographer has been paid for taking is vested in the sitter, but the negative is his property. This has been pointed out in these pages over and over again. Yet here is a case where the photographer does not seem to be aware of the fact that the sitter is not entitled to it, and cannot legally claim it in a court of law.

The other query, above alluded to, is quite a different one, and is one that some who may contemplate taking action for infringement of their copyright will do well to consider, from a business point of view, before commencing proceedings. Briefly, the case is this. The photographer granted permission to a local stationer to reproduce a copyright portrait of his as a picture-postcard on condition that his name and the word "copyright" appeared on the cards. Whether payment was or was not made for the privilege is not mentioned—but that is of no moment. The permission was given. Then a local newspaper reproduces a portrait from the post-card and credits the stationer for it, and makes no mention of the photographer whose copyright it is. The latter then consulted his solicitor, who, of course, told him that

he had cause of action against the newspaper, and advised him not to take proceedings, because, in his opinion, the damages he would recover would not exceed five pounds, and even if this sum were awarded by the court it would not more than pay the expenses. He added that if it were proved that the reproduction in no way injured the sale of the prints from the original negative the damages might be but a farthing. This would usually not carry costs. We have briefly quoted our correspondent's letter, which is published at some length elsewhere, and he is evidently not altogether satisfied with the opinion of his solicitor, for he appeals to us for further advice as to whether he should proceed against the paper or not. We think the advice given by the solicitor sound and good, for what is the use of going to law if nothing is to be gained by the litigant? Such actions are only good for the lawyers. What is the advantage of obtaining a small sum by way of damages if the cost of obtaining them is more than swallowed up by the expenses?

To recover damages in any lawsuit it is necessary to prove, to the satisfaction of the court, that actual injury has been sustained, and in such a case as that in question it would be very difficult on the part of the plaintiff. Our correspondent sent us a copy of the portrait as it appeared in the newspaper, and we should surmise that it would be next to impossible to prove that the publication of such a print could in any way affect the sale of those from the original negative. Indeed, if we were the owners of that we should be pleased that our name as the producers of the photograph were omitted, for we should consider that it would not redound to our credit to have our name associated with any such reproduction. Be that as it may, we imagine that in a case like this it would be very difficult for the most clever counsel to convince a jury that any real injury had been done, such as would induce it to award anything beyond quite nominal damages. *Amour-propre* and business are different things. No one likes his works, whether copyright or not, copied without his sanction or without his name appearing in connection with the reproduction, but let us just look at the business side for the moment.

Usually, when a publication has pirated a photograph and attention is called to the fact that it is copyright, the proprietors of it are generally glad to pay a sum to the owner in order to avoid litigation. When that sum is fairly reasonable, in the circumstances, the photographer will do well to accept it—together with the costs—as between solicitor and client. These latter should always be insisted upon, if the services of a solicitor have been invoked, as they are always an item to be considered. When this course is taken, the photographer is sure of a certain amount without further anxiety, which is not always the case if the matter is taken into court and the verdict rests with a jury.

THE World's Fair at St. Louis is apparently not exciting the universal interest which the promoters expected. It is too early to predict a failure, but, according to the "Daily Telegraph," ominous stories are afloat concerning the attendances and small receipts. The Government has lent nearly a million sterling towards the exposition and fear is entertained lest a Government Receiver should be appointed to run the business and secure reimbursement. The chief complaint made here is that the advertising department at St. Louis while possessing large funds, lacks capacity and originality in placing its attractions before the public. Mr. Secretary Shaw has already communicated with the president of the exposition concerning this matter. By the terms of the loan it is expressly provided that the Government shall have power to step in and manage the show in default of payment of the first instalment, which was due on June 15.

A PHOTOGRAPHIC LIBRARY.

The following lines have been written in response to the Editor's suggestion that the Jubilee Number of his journal should include a contribution from the writer's pen. The appearance of this article when the Jubilee is a thing of the past unfortunately due to pressure of official duties; but the writer is glad even at this late date to associate himself with the event, and to join those others who have tendered their congratulations to the Editor on the completion of the fiftieth year of his paper, and their best wishes for its continued prosperity.

A photographic library for subject matter is perhaps poor material with which to angle for attention; but the writer hopes that a little contribution on the subject may arrest the eyes of a few at this Jubilee time, when, to hark back and review the history of photography is perhaps not devoid of interest.

It may be too much to lay down that England possesses the

graphic age that it almost entirely lacks the old volumes in which early philosophers and investigators recorded those observations which form the basis of photography, and which in later years have been intimately linked up with the more recent discoveries that go to make up the photography of the present day. For these one must go to private collections, or that first and last source of information, the splendid library of the British Museum.

The writer may be excused by no means a new lament when he expresses regret that the Society for the greater part of its career has had little, and for a long time no, accommodation in which to treasure up the books and publications which record the story of photography. Twelve years ago its library was less than commonplace, and entirely unworthy of the first society in the country.

That it had from time to time many books which still do not find a place on its shelves is apparent from the early files of its Journal. For years it did not possess a complete file of its own organ, "The Photographic Journal," and its collection of other publications, was equally incomplete. The Society had before it, however, better times, and with an ability to command premises of its own the expansion of its library was one of the most obvious duties falling upon its officers. To the writer's predecessor is undoubtedly due the placing of the library upon a creditable basis. In those days it was possible to acquire batch after batch of books, few, if any, of which were upon the shelves, and the work would have proceeded faster with a command of more funds. The R.P.S. library was not the only one at the time to which attention was being given, and in consequence a good many exchanges of duplicates were possible. This process of adding to the library has long since become less productive, and while the Society still wants a number of important works or editions, the task of bringing them to light is growing increasingly difficult and unencouraging by the lack of any success.

To make an end of regrets, however, it may be taken that the library was first deserving of a catalogue in 1893, and one giving full titles was issued in that year. It is a pity that it was arranged only under author's names, but it served, in addition to its more legitimate purposes, to interest in the library a good many who commanded still missing books or editions, and further additions were made.

That catalogue of 1893, the first issued by the Society, has long since been out of print and hopelessly out of date because of the growth of the library since its publication. In the last decade the Society has seen to it that the future members of the Society will be unable to regret the neglect of contemporary works, to the acquisition of which a respectable sum has been devoted every year. But there are still many books which, by their absence, rob the Society's library of its value. It would appear that the best means of discovering these missing books is to advertise the wants, and this the writer proposed to do through the medium of the new catalogue. The idea was to make of the new catalogue a complete list of photographic books and periodicals, whether in the library or not, those in the Society's possession being sufficiently indicated to make it serve the double purpose. An obvious step in this direction was, of course, the combination of the existing printed catalogues of the societies named, with a number of others, amongst which that of the Dansk Fotografisk Forening of Copenhagen is worthy of notice. But it became apparent that the publication of the new catalogue would be unduly and, in the opinion of some, unnecessarily delayed, and the scheme in question has been set aside. The writer would like to see such a catalogue, however, from the point of view of its value as a complete bibliography of photography, and that, also, of its utility as a means of advertising the Society's wants; but for the present it is no longer under consideration. It may be of interest to point out that the

A. W. W. BARTLETT.

Secretary "Royal Photographic Society of Great Britain."

st photographic library of to-day; but in the Royal Photographic Society's collection this country undoubtedly commands a place which is entitled to rank amongst the foremost.

In many respects this library has no peers, but in some other respects it is closely run, if not excelled, by the valuable collections brought together by the Camera Club of New York, the Société Française de Photographie in Paris, and the London Camera Club.

The present reference to the subject is suggested by the impending publication, in the autumn, of a new catalogue of the Royal Photographic Society's library, which is in the writer's charge; and the opportunity, afforded by the retrospect associated with a celebration of this sort, of drawing attention to a matter which has a very real claim to the notice of those who attach importance to a proper record of photographic movements and things.

The R.P.S. library belongs so essentially to the purely photo-

defect of the former catalogue—the omission of a subject classification—will be remedied, and the writer hopes that his present early reference to the subject may be a means of enabling him as librarian to get into touch, before the date of publication, with some of the many at home and abroad who must still have editions of old books and early volumes of old journals which are at present conspicuous by their absence in the library at Russell Square.

One may be asked: What is the use of all this? Does the creed of the librarian and the book-collector commend itself to the photographer? The answer may not be altogether a rosy one, judging by the amount of interest shown in the making of the library in the first thirty-five years of the Society's existence; but one must not forget that not everyone responsible for our literature is encyclopædic, and that when a library is referred to it is in the majority of cases consulted in the interests of the many. For this reason it is to be hoped that the present appeal for co-operation, which the Editor kindly permits the custodian of the library in question to make, may not be made in vain. The collection of books is now so good that it ought to be better, and if only a dozen additions result, the writer will feel well paid for his trouble.

Much more might be written about the contents of the library, and about a photographic museum which goes hand in hand with a photographic library; but these were not contemplated in the present notes, which have already absorbed perhaps more than a due proportion of these pages.

A. W. W. BARTLETT.

SOME DISCURSIVE REMARKS ON ORTHOCHROMATIC PLATES.

I.

PERHAPS owing to the increased attention that has lately been paid to colour photography generally, or to a better appreciation of the failings of the ordinary plate in colour rendering, there is no question that colour sensitive plates are more generally used than they were a few years back; and something, too, is due to the fact that it is now almost universally acknowledged not only that such plates keep as well as non-colour sensitised, but that they will do all that the ordinary plate will do, and, as a rule, a little more besides.

The terms ortho or iso-chromatic are not legitimately applicable to any plate—the former because no plate gives absolutely correct visual rendering, and the latter because no plate gives absolutely equal colour rendering, and if it did it would not be correct. Panchromatic seems more justifiable. It must not be overlooked that in a colour sensitive plate there are two distinct positions of sensitiveness, the one belonging to the bromide, or bromoiodide of silver itself, and the other belonging to the bromide + dye; these may merge the one into the other, though it is a little unusual, but we must recognise their existence as separate, and, whilst we can increase the sensitiveness of the plate to those rays visually most luminous, the sensitiveness to the blue and violet still remains abnormally high, and entirely wrong according to the visual impression. If we set the visual luminosity of the yellowish green, near the well-known sodium or D lines, as 100, that of the blue, between F and G, the position of maximum photographic sensitiveness, is only 10; whilst at this position the photographic luminosity is 1,000 and that of the yellow-green only 10, with an ordinary plate. It will be obvious, therefore, that we must enormously increase the photographic action of the yellow-green if the blue sensitiveness is to remain constant, but if we reduce this by the use of an absorbent medium, in the shape of a yellow screen, then the task of yellow sensitising is not such an impossible one.

This absorption of the blue and violet is the sole purpose of a yellow screen, and the most perfect one is that which, whilst

absorbing the more refrangible rays, transmits the others without any reduction. In this respect all the commercial glass screens are unsatisfactory, not only because they are not a pure yellow, being more orange, but because they contain a considerable percentage of black, which degrades the whole of the spectrum. With all, or at any rate the majority of commercial ortho plates, there is a peculiar drop or minimum of sensitiveness in the green-blue, between the E and F lines. This characteristic of all dyes of the fluoresceine family, which includes, of course, the eosines and erythrosines and any orange tint in a screen absorbs more or less of this green-blue, and therefore makes matters worse. This minimum is particularly noticeable with short exposures, but even itself out with full exposures. Excellent screens can be made with tartrazine, naphthol yellow, picric acid, and ammonium picrate; less satisfactory ones with acridine yellow, aurantia, uranine, Madder yellow, etc. A solution of tartrazine exposed continuously to white light alters in colour, becoming more greenish, but I am not aware that such action is to be detected when used in the ordinary dry filter form. Any green in a filter, except, of course, for special work, is a mistake, because according to its tint it absorbs more or less red or orange, and this makes the photographic action of these colours worse.

There are, of course, commercial screens, such as Cadett's, which have a pronounced orange colour, but it must not be forgotten that they are adjusted to one plate, and for a special purpose, and therefore do not come into consideration as generalities.

M. Vidal and the late W. K. Burton were the first, I believe, to suggest that the yellow screen should be put in the plate itself by staining the gelatine, in which the silver salt is embedded, with ammonium picrate. This idea has lately been revived and the following solution recommended:—

Ammonium picrate	0.65 g.
Dextrine	2.5 g.
Distilled water	100 c.c.

In this the colour-sensitive plate is bathed, then rinsed in water and dried. The disadvantage of this process is that it reduces the general sensitiveness to white light, or, in other words, slows the plate, which is not always required, because one may wish to give an extremely short exposure to an ortho plate, and this would lead to under-exposure.

The excellence of commercial ortho plates is so high now that there is little inducement for the average worker to dye his own plate, except he wishes to specially sensitise for red with one of the new cyanines, and it is not a job that I can recommend, as the pitfalls are many. In the first place, the composition of the emulsion is to the plate user an unknown quantity, and it is not every emulsion that can be satisfactorily colour-sensitised, for as a rule plates rich in iodide, for instance, do not take kindly to the process; the presence of free bromide is another and an important factor; then, again, some plates will fog, and this is frequently due to slow drying, and others to a high temperature in drying. Some will not stand ammonia, nor will some dyes, though if one works to a given formula this point is generally determined for one.

Yet another and an extremely important point is to ensure that one obtains exactly the dye recommended, for every aniline dye maker seems to issue what he thinks he will under a common name. As an instance of this, I may cite that I have seven erythrosines, obtained from different sources, and only two are the same in sensitising action, and one of these differs from the other when used as erythrosinate of silver. Again cyanine never seems to be pure; some samples give perfectly clean plates, others fog badly, and others slow the emulsion more than others. Eder's method of treating it with hydrochloric acid and evaporating to dryness does not, as stated, convert it into chlor-cyanine, the ordinary variety being iodo-

ine, but it certainly improves it. The new cyanines, ethyl orthochrome, pinachrome, and Miethe's latest irisine, will probably entirely replace the ordinary cyanine, as giving better and general sensitiveness, and they are all of them pure.

At present we have no information about irisine other than that it is made by substituting a monatomic complex of the iodine in ethyl red, and it is, I gather, the nitrate of ethyl red, and, according to Miethe, sensitises well for red, perfectly clean plates, and is likely to be of great value. Surprisingly enough, orthochrom T in my hands has been a complete failure, always giving fog, but this is probably because I have not happened to have hit on the emulsion that it suits.

Sensitising plates by bathing, one must not forget that a yellow stained plate is not necessarily of higher colour sensitiveness, because one has simply stained the gelatine more. An ideal plate would probably be that in which the silver halide molecule alone was stained and the gelatine colourless, the essential principle of colour sensitising is that the dye salt should combine with the dye. Excess of dye can stain the gelatine, and then acts as a screen, and, as most dyes show sensitising action at the position of their maximum absorption, though in some cases the two are not absolutely coincident, the shifting of the sensitising being a few wave-lengths, it may well happen that the excess of dye acts as a screen to the very rays for which it sensitises; as well, therefore, to rinse the plate thoroughly after bathing, and I prefer to then place it on a whirler for a short time to rid of any adherent drops of water.

In the early days, and even now with collodion emulsion, or compounds of some dyes, particularly eosine and erythrosine, dissolved in ammonia, were and are used, and certainly the erythrosine silver bath gives very satisfactory results regarding colour sensitiveness, even with gelatine plates, they will not keep more than a few days, and I have always used, even with collodion emulsion, and much more so with irisine, that fog is almost invariable when an alkaline developer is used, unless the plate be first bathed in a weak bromination, about 0.5 per cent., then rinsed and developed. There are many other dyes which also give good results with silver emulsion, but as, except in one or two cases, equally satisfactory sensitiveness may be obtained by other dyes without silver, it is not necessary to deal with them.

E. J. WALL, F.R.P.S.

NEW LINK BETWEEN CALCULATING AND EFFECTING CAMERA EXPOSURES.

[A paper read before the Royal Photographic Society.]

The better type of hand-camera the user is provided with means of altering the lens aperture, and varying the shutter speed. These adjustments are valuable if used rightly, but a source of error with many, for an alteration of the one requires alteration of the other, and as these alterations are often made in the hurried moment before an exposure, with perhaps unaltered light to deal with, it is no wonder that mistakes are made.

Shutter makers and lens makers have hitherto done practically nothing to ensure the right stop being used with the right shutter speed (or vice versa), and the object of my paper is to show a means by which the chances of error are reduced to a minimum.

Let us examine in the first illustration (Fig. 1) the scales as usually provided. The bars with pointers represent the movable parts, the figures being on an immovable part. In the diaphragm scale of all iris diaphragms I have seen (except some made in my own workshop), the divisions between the standard stop numbers are unequal, becoming smaller with the smaller size diaphragms.

In almost all scales of shutter speeds the divisions are still more irregular, the one illustrated (copied from a well-known shutter) having the space between 1-5 and 1-25 less than that between 1 and $\frac{1}{2}$. I have only seen one instance (a pneumatic blind shutter of Newman and Guardia) in which the divisions were uniform.

In the next illustration (Fig. 2) I show the same moving parts and scales for the same purpose as before. But three points are essential to my purpose are observed. Firstly, the moving parts are brought into fractional contact. Secondly, the long exposure end of the exposure scale is at the same end as the

Fig. 1.

small diaphragm end of the diaphragm scale. Thirdly, there is a uniformity between the two scales, the distances between figures, which halve or double, being identical throughout. Thus the distance between 1 and $\frac{1}{2}$ is the same as between 1-32 and 1-64, and as that between $f/8$ and $f/11$. In short, the scales are logarithmic. It will now be seen that a great practical advance is secured, for if both moving parts are moved together either up or down the scales, the opening of the diaphragm is automatically compensated by a shorter shutter speed and vice versa. In fact, the camera user who wishes to alter either the shutter speed or the stop can do so with confidence without altering the total light effect on the plate. This

Fig. 2.

of course is presuming that the speed figures represent true effective exposures on the plate, which, by the way, is sometimes a rash presumption. If, therefore, the right exposure is secured by using a certain stop with a certain speed, the same exposure effect is automatically secured with an altered stop and speed.

This, the effecting a camera exposure, is only one step in the method I am describing, and I have not yet touched upon the link mentioned in the title.

I have, by the way, used the word "new" for the method, as it has not been described before a society or in the press.

But it is really four years old, my patent on the subject being dated March, 1900.

And now a few words on calculating exposures.

The factors influencing an exposure can usually be condensed to three, viz.:—light (whether estimated by actinometer or tables), speed of plate, and diaphragm. These, with the resulting value of exposure, are the four values which come into the calculation.

The most obvious and simplest way to estimate from these factors is by the ordinary single slide rule, as in the Bee Meter. And this obvious way possesses the commercial advantage that one is able with it to bewilder the public with reference to "one movement of one scale."

But there are innumerable ways of arranging a slide rule or slide rules to attain the same end. For our present purpose it is sufficient to describe one. Two movable slides (Fig. 3) work side by side. Each carries a scale, one for light values, the other for plate speeds. To each slide a pointer is attached, indicating on scales on the fixed part of the instrument, these two last scales (the outer ones) being for diaphragm and exposure. The instrument is set by setting the plate speed against the light value, and then moving both slides together until the left-hand pointer indicates the diaphragm used; the other pointer will then indicate the exposure. The peculiarity of this arrangement is that when plate value is set against light value,

PLATE		LIGHT	
	8		
F45	16	2	1
F32	32	4	1/2
F22	65	8	1/4
F16	130	16	1/8
F11	250	32	1/16
F8	500	65	1/32
F5.6		130	1/64
STOP		EXP.	

Fig. 3.

the two pointers will always indicate a diaphragm and an exposure which when used together will be correct, and this holds true if the two slides are together moved up or down. The divisions of the scales are of course logarithmic. Thus if plate 130 is set to light 16, and the pointers indicate $f/22$ and $\frac{1}{8}$ exposure, the same total light effect on the plate will result if the slides be together moved downwards and the values indicated—say $f/8$ and $1/64$ exposure—be utilised.

I think that if this slide rule is kept in mind, and that if we go back to the previous illustration (Fig. 2), the link between calculating and effecting will become plain.

We have only to divide the two movable bars logarithmically, and add figures for the plate and light scales, to have a calculating shutter in which the act of making the calculation, setting plate speed against light value, automatically sets the diaphragm and shutter speed in such a relation to each other, that a correct exposure results whatever diaphragm is indicated and used.

I have shown these movements as in straight bars, but the plan equally applies with the circular scales of iris diaphragms and modern between lens shutter. In fact, most of my trials have been with the circular form. I will try to illustrate this form with a "lever" lantern slide.

I also threw on the screen a photograph (Fig. 4) of a meter shutter with circular scales made on this system, and you will

have the opportunity of examining this shutter, which, however, is by no means final in construction.

It is, I think, a convenience to add to the plate scale adjustable marker, consisting of two pointers, a long and short one. The longer pointer is placed over the speed of the plate in use, and saves selecting this speed from a set of figures. In a full exposure the long pointer is used to indicate the light value, and for a minimum exposure the short pointer.

The movable ring or bar which adjusts the shutter speed and also carries one of the scales, is "frictioned on" to a similar ring or bar, which adjusts the diaphragm; so that when the diaphragm ring is moved it carries with it the exposure ring, unless the latter is held, and the movement of the one exactly compensates, as regards light action on the plate, the movement of the other.

The simplicity attained in use of this "link" is very striking. The act of moving one slide (holding the other) so that the pointer indicates the light value, not only makes the required calculation, but automatically sets diaphragm and shutter speed to such a relation that a "correct exposure" results when made. One movement will then alter to any required diaphragm, or shutter speed, without disturbing this relation.

So far all appears smooth sailing, and I have given no indication

Fig. 4.

of the difficulties which stand in the way of constructing such an appliance.

Both in iris diaphragms and in shutter speeds the habit makers has been to construct the mechanical part, and then mark the position of stops and speeds at whatever part of the scale they chanced to come. But in this appliance, uniform logarithmic divisions on the scale are a necessity, and the scales have to be constructed first and the iris and shutter built to fit them. This really means the redesigning of both.

As regards the iris diaphragm, the difficulty has been overcome by the mechanical foreman in my own workshop, who has designed the necessary form.

As regards the shutter, the diversity and choice of construction is so great, and the inherent defects of each construction so manifest, that after four years' application to the task, with much aid from a skilled mechanic, I cannot claim final success, although it may come any day. It is possible to provide a shutter which will fulfil the conditions (subject to the imperfections of all shutters), but not easy to do so in a commercial form.

Perhaps the existing form of shutter most readily adapted

ld be the Newman and Guardia type, the front of the era being given up to the shutter, and the speed decided varying escape of air from the pneumatic cylinder. This d adjustment conforms to the logarithmic scales with little culty.

the compact shutters of the Bausch and Lomb type, which open and fly shut quickly (even at slow speeds), the difficulties are greater, and the speeds are best made to conform the logarithmic scales by means of a circular cam, which be shaped to press upon a speed lever to any desired unt at any selected point of the logarithmic scale. I find the recent Volute shutter can be fitted with my calculating es with but little alteration, and I show a rough example. In this shape of shutter there is usually a defect caused by sudden check at the end of the fly-open movement, and h makes the speed from $\frac{1}{4}$ th to 1-25th uncertain.

must also be remembered that a photographic shutter of necessity, an imperfect appliance; for it is an aperture, a point, which has to be uncovered, and while the aperture n course of being uncovered only partial efficiency is ined.

With present appliances the photographer may put up with e many defects without even discovering them. But with the er shutter I have been describing he is invited to discover n by the means which are provided. For instance, the

PLATE LIGHT			
F45	8	2	1
F32	16	4	1
F22	32	8	1
F16	65	16	1
F11	130	32	1
F8	250	65	1
F56	7	6½	6

Fig. 5.

ter is set to $f/8$ and 1-64, and a plate exposed; the two es are then moved together until they indicate $f/45$ and $\frac{1}{2}$, another plate exposed. When developed together the ult will soon show whether the effective values of the cked speeds were relatively correct.

With the "fly-open" type of shutter the short exposures are ntively much less efficient than the longer ones, and to mpensate this error it will probably be necessary to intro-e a compensating error into the logarithmic scales. If six the exposure divisions occupy the space of seven of the hragm divisions it will be about right. The two inter-iate scales must then have divisions of intermediate length. s is shown in Fig. 5.

on shutters (as in most of Newman and Guardia's) where the osing plate moves at a uniform speed throughout its action, a speed being alterable, the same error does not arise, as long exposures have the same relative inefficiency as the rt ones, and the compensation I mention will probably not required.

There are two distinct ways in which the methods I describe e, be partially adopted, and very considerable advantages tured, although not the full advantages of the complete thod.

The first is to apply the two slides to a shutter (other than etween lens shutter), the one slide being attached to the speed ustment, and the other merely indicating on a scale the

diaphragm to use, or which it is proposed to use. In this method the diaphragm (a separate appliance) has to be set by hand in the usual way. This would probably be the application for focal plane shutters.

The second method is to apply the two slides (in the form of rings) to the mount of a lens, the one slide forming the usual ring of an iris diaphragm (which must be constructed to indicate on logarithmic divisions) and the other indicating on a scale the exposure to give. The exposure is then effected by hand or by shutter.

In the light scale of these slide rules I have adopted a simple figure to denote the value of the light falling upon the subject, and have assumed that this light value be ascertained by means of an actinometer. I regard this as by far the simplest and most complete way of ascertaining the light value.

But for those who prefer to ascertain the light value by computing it from time of year, time of day, state of atmosphere, and class of subject, the same scales will still apply, as Burton's well-known table (multiplied by 2) will give an estimated light value, Burton's standard for best mid-day summer light being 1, and mine being 2. To apply this exposure table plan it might be advisable to add an additional movable scale of pointers on one of the movable slides to provide for the elaborate classification ranging between landscape and portraits indoors, which is necessary in the exposure table plan, but unnecessary in the actinometer plan.

ALFRED WATKINS.

PLATINUM PRINTS WITH GLOSSY SURFACE.

A WELL-KNOWN superiority of the platinum print is the deep, saturated coloration of the shadows, which can be obtained by this process. The matt surface of the platinum print, its pure black tone gradations to the deepest shadows, remind more of the superiority of photo-engravings, than the traditional reddish-brown glossy albumen and collodion prints, and we imagine the former, therefore, to be more artistic than the latter. But the platinum printing process puts some high demands on the negative, which are partly conditional by its want of gloss. The covering of the lights must be in such a way, that the shadows have reached the deepest blackening, when the details in the brightest parts of the picture are printed out. If the negative is less covered, the shadows will be without the necessary strength, if abundantly covered, the details will disappear in the shadows. To this may be added, that on account of the peculiar gradation, richly detailed shadows cannot easily be obtained upon platinum paper. The print shows a very handsome shading in the lights, pronounced "high lights," but an unsatisfactory gradation in the dark tones. For this reason the process is preferably used for light subjects with limited shadows, and for reproductions of paintings the carbon print is given the preference. But if a glossy surface is given to the platinum print, even weaker covered negatives will give yet sufficiently strong pictures, and the details in the broad shadows become visible, because the colouring platinum is then in a transparent layer, whose "depth structure" can be distinctly recognised. For this reason it is justifiable, to produce in certain cases glossy platinum pictures. Henry Dietrich gives in the "Photographic Times" Bulletin for May a translation of A. Von Hübl's method of obtaining such prints. He says: "As glossy coating I have selected gelatine, and it is peculiar, that this body, which prevents the formation of brown tones, if present in only small quantity, facilitates this coloration, if the coating is put on so thick, that the picture will not originate any more on the paper fibre, but simply upon the gelatine. The paper—principally coarse-grained drawing paper—is coated with a uniformly thick gelatine solution. The paper is moistened and squeegeed upon a horizontal glass plate, the edges of the paper are turned up and the gelatine is poured on. For a paper surface of cm.^2 about 10 c.cm. gelatine solution 1:20 are used.

A tanning of the film is not necessary, as this is done so completely by the sensitising, that the paper will stand a hot development. Strongly gelatinised drawing paper is very uneven after drying, it is therefore necessary to tack it to a drawing board before sensitising

and let it dry on the board. The sensitising has to be done rapidly to avoid stripes. For black pictures it is composed of 4 c.cm. iron solution, 1.5 c.cm. potassium chlorure of platinum 1:6. To this developer are added 2 c.cm. platinum solution to 50 c.cm. oxalate of potassium 1:4. For development, prints of larger sizes are tacked again upon a board and the solution is put on rapidly and uniformly with a brush or sponge. If hot development is applied, the print is simply drawn through the heated developer. Stripes or other defects will seldom or never result from this operation. For brown pictures, mercury salts are added to the sensitising solution or the developer. The sepia brown pictures do not consist, as formerly accepted, of brown metallic platinum, but to a great extent of a brown mercury-platinum compound. In strong acids, chloride of copper or chrome acid, they will bleach out rapidly, but they resist completely the atmosphere and all atmospheric influences.

If a paper, coated with a sensitising solution containing mercury, is developed after printing, two processes run parallel. On the one hand, black metallic platinum is secreted from the platinum salt, and, on the other hand, the mercury salt is reduced to an oxidal salt, and this unites with the chlorure of platinum to a brown compound. From the relation of the black platinum precipitate to the brown compound depends the colour of the picture. But these two processes, according to circumstances, pass at a different rapidity, and it may happen, that in the lights only brown compound, and in the shadows only the black platinum, is secreted. Such double-toned pictures do not make an agreeable impression. To produce pure brown tones, the reduction of the platinum has to be counteracted, and that of the mercury salt has to be increased. The former is done by the addition of much acid to the sensitising solution and the developer, the latter by the application of easily reducing mercury salts, for instance, citrate of mercury. For the production of sepia pictures upon strongly gelatinised paper, the following sensitising solution is used:—

Iron solution	20 c.cm.
Potassium chlorure of platinum 1:6	8 c.cm.
Citrate of mercury solution 1:30	+5 c.cm.
Citric acid solution 1:2	5 c.cm.

Four c.cm. citrate of mercury solution give prints of pure sepia colour, and, by reduction respectively increase of this addition, the brown coloration can be changed from brown-black to sepia red. Unbroken, light brown or reddish sepia tones can be found suitable only for certain subjects, while the black shades, with only traces of mercury, result in a rich scale of generally useful colour tones.

For development the following solution will serve:—

Oxalate of potassium	200 g.
Citric acid	20 g.
Water	1,000 c.cm.

If 10 to 50 c.cm. of citrate of mercury solution are added to this solution, the quantity of mercury in the sensitiser can be restringed, and the development will then proceed quicker. The pictures can be developed cold with the brush, or hot; in the latter case, somewhat lighter, purely brown shadows are obtained. One defect, which has not been entirely removed yet, is that with a large quantity of mercury the lights show sometimes a yellowish coloration. This general tone shows itself mostly after fixing during the washing of the prints, and may be ascribed to some extent to a further action of the light upon the sensitising—and developer rests, remaining still in the paper. At all events, such prints should be held in the dark until washed. The gloss of the picture depends essentially upon the treatment of the paper. If put into the drying closet in a still moist condition the gelatine film will soften and dry with a gloss; but if it is left to dry in an ordinary temperature only a matt gloss is obtained. If developed hot high gloss will always originate. If this is to be avoided the gelatine solution must be mixed with arrowroot.

These pictures can also be varnished. For this purpose Damar varnish, and also the ordinary negative varnish, can be used. In the latter case, the print should be heated previously, and the varnish applied with a flat brush, and dried afterwards by heating."

Mr. W. G. Moore, photographer, of 11, Upper Sackville Street, Dublin, has added a photographic material department to his business.

THE THREE-COLOUR PROCESS.

The following correspondence and articles appeared in the number of the "Spectator":—

THE THREE-COLOUR PROCESS.

[To the Editor of the "Spectator".]

Sir,—Messrs. Cassell are not in the habit of complaining of reviews of books published by them, and they fully recognise the general fitness of the literary notices contained in the "Spectator"; but a paragraph purporting to be a review of a very important work theirs—"The Water-Colour Drawings of J. M. W. Turner, R. in the National Gallery"—appeared in your issue of May 21 which they cannot pass without protest.

Your reviewer has evidently gone upon the assumption that an attempt to reproduce Turner's water-colour drawings must necessarily result in nothing but a "travesty" of the originals; and has certainly not taken the pains to see for himself what is possible even in reproducing Turner.

Possibly in the past he may have seen work by the three-colour process that he did not like, and doubtless in the stages of progress which have led up to the success of the process which has been achieved indifferent results were a necessity. But it is surely to that your reviewer acquainted himself with the progress that has been made, and revised his judgment. Messrs. Cassell do not claim that the work is perfect, and that no further improvement is possible; but they do claim that no better work of the kind has ever been done, and that no artist was ever on the whole so satisfactorily reproduced in colour.

You will observe that this is not a question of opinion, but of fact. It is not a question as to whether your reviewer likes or does not like three-colour reproduction, but as to whether these reproductions fairly represent the originals, a matter that can be judged of by even an artist as well as by a literary reviewer, and I shall be glad if you will put by the side of your reviewer's flippant treatment of the book the opinions which I subjoin. They are a few only of many, but they are, I think, a sufficient reply to what appears to me to be the uninformed prejudice of a literary reviewer in dealing with an artistic matter.—I am, Sir, etc.,

EDWIN BALE, R.I.

(Art Director, Cassell and Company.)

La Belle Sauvage, Ludgate Hill, London, E.C.

Sir E. J. Poynter, Bart., P.R.A., writes:—"The reproductions of masterpieces, and the book will be a delightful possession."

Mr. Hawes Turner, Keeper and Secretary of the National Gallery, writes:—"The coloured reproductions are undoubtedly the best hitherto attained."

Mr. George Clausen, A.R.A., Professor of Painting at the Royal Academy School, writes:—"One can turn to the book again and again as one can to the fine originals. . . . Indeed, the reproductions are as good as the drawings."

Mr. Alfred East, A.R.A., writes:—"It is a splendid volume, and a tribute to a great artist."

Mr. B. W. Leader, R.A., writes:—"I think the reproductions of the most successful I have yet seen in any publication of the kind."

Sir Ernest A. Waterlow, R.A., President of the Royal Society of Painters in Water-Colours, writes:—"I made the acquaintance of the work some little time ago, and think the reproductions excellent. To the busy man who has little time to visit galleries the work will prove a boon, and will, I am sure, be highly appreciated."

[Our Art critic deals with the three-colour process elsewhere, and with the not very courteous suggestion that our reviewer had "certainly not taken the pains to see for himself what is possible, even in reproducing Turner." Before we leave the subject, however, we must point out that no attack was made upon Messrs. Cassell, or upon their use of the three-colour process. The contention of our reviewer was merely that the three-colour process, by whomever and wherever used, does not, in fact, give a true representation of the picture depicted. He did not, that is, accuse Messrs. Cassell, or any other publisher, of defective work, but merely insisted, as he had every right to insist, that the three-colour process does not give us Turner colouring. If a critic is not allowed to say this of a mechanical process, criticism becomes a farce. As a matter of fact, we believe that the best artistic opinion in the nation will be with our Art critic. The three-colour process has beauties of its own, and whose designs are specially made to be reproduced by it, it is often very

ant to the eye. To pretend that it reproduces the glories of
er's palette is absurd.—ED. "Spectator."]

The "Spectator" of May 21 there appeared a short notice of a book
productions of water-colour drawings by Turner in the National
Gallery. In this review, to the authorship of which I must plead
guilt, I declared that the three-colour process was wholly incapable
of reproducing the wonder and subtlety of Turner's colouring. This
spoken view has been challenged by the publishers of the book in
question, Messrs. Cassell and Co., and their art director, Mr. Bale,
written a letter of protest, which appears in the present issue of
"Spectator."

The first charge which he brings is that the reviewer "has certainly
taken the pains to see for himself what is possible, even in re-
producing Turner." Let me assure Mr. Bale that I have a deep
gratitude for first-hand information, and that I took the book in question
to the National Gallery and compared its reproductions with the
originals, making notes in the margin of what appeared to me to be
grosser errors of the process. Mr. Bale asks that I should make
myself acquainted "with the progress that has been made," and
use my judgment. But what more can I do than study his book,
which he seems to regard as reaching hitherto unattained heights of
reproduction—though here there is a note of modesty, for we are
told that it is not claimed "that the work is perfect"? This apologetic
attitude suggests the famous dancing dog of Dr. Johnson, and
may truly say of this colour-printing that "the wonder is not
that it is well done, but that it should be done at all." Indeed,
there is something marvellous in the fact that minute dots of three
colours mechanically placed side by side should produce even a re-
semblance to painting. But then the question arises—Is the result
justified by its beauty and nearness to the original? The whole
point is that these reproductions claim to represent the colour of the
original with something of the same accuracy that a photograph
represents the form of a picture. I have open before me as I write Mr.
Bale's print of Turner's "More Park" ("Rivers of England," No. 18),
the margin of which I noted in the National Gallery what
appeared to be the differences between it and the original. (I
could here like to point out that these notes were the result of an
unprejudiced study made before any controversy had arisen.) If

Mr. Bale cares to compare the print and the original, I think he
will find that the sparkling lights in the trees on the right are not
in tone or colour, that the edge of the reflection beneath them is
hard and dark, that the piece of earth beneath these trees at the
bottom of the picture is too hot and red, and that the red in the
trunks of the lock is wholly false. If the sky is examined it will
be clear that the blues have a tendency towards a dirty purple, and
that there is an exaggerated spottiness of this colour quite foreign
to Turner's sky. Also, the pale warm lights are dirty, and the
principal light in the sky over the hill is lost. After I had made a
careful examination, I placed the book by the side of the original,
I walked across the room to study the effect at a distance. The
result I recorded in the following note: "Looking at the print and
the original side by side at a distance, when the form is not seen
clearly, it would be hard to tell that the print was intended as a
copy of the colouring of the water-colour." I will not weary the
readers of the "Spectator" with the notes I made of several other
drawings, all with like result. But I wish to show that my dislike
of the process is the result of study, and not, as Mr. Bale says, "the
informed prejudice of a literary reviewer in dealing with an
artistic matter."

Mr. Bale twice in his letter alludes to the "literary reviewer."
By this term I make no objection; there is something flattering and
humiliating about it, for does not the amateur of an art always wish
to be considered a professional? But I cannot lay claim to this
honourable title. I can only claim that of *pictor ignotus*, hoping
at the constant, though humble, practice of painting enables me at
least to appreciate the art of others.

The real importance of the question of the three-colour process lies
in the fact that a great many people who have not the leisure or the
willingness to enable them to judge of it independently are wont to
assume that because it is a mechanical process based on photography
it is therefore accurate. This assumption is misleading, because it
leads to the falsifying of ideas about the colour of pictures. There
is in a book by Mr. Lewis Hind, published by Messrs. Black, a re-

production of the picture of the "Death of Procris," by Piero di
Cosimo, in the National Gallery. The colour of this print, even if
slightly gaudy, is not unpleasant, but it is not the colour of the
original. The sky of Piero is a warm grey-blue, and not the colder
and greener hue reproduced. Neither is the grass the cold green of
the print, nor does the blue hill contrast so strongly with the satyr's
face and arm in the original as in the copy. There is another ques-
tion, and that is the variation between the different impressions of
the same picture. The advertisement of Mr. Hind's book contains a
specimen print, which, if compared with the same picture in the
book, reveals little differences. The picture represents a flock of
sheep near some blossoming trees, and has a sky with large cumulus
clouds in it. In one copy the sheep are much bluer in their shadows
than in the other, and the same colour has got into the tree-stems.
The clouds, too, are warmer in the whites in one version than in the
other. Now, which of these am I to accept as the representation of
the original? They cannot both be right. Obviously the personal
equations of the printer and of the photographer have entered into
the result. Hence the prints are only copies in which the copyist
uses an elaborate mechanical apparatus instead of a brush. Just as
several copies by the same painter will differ from their original, so
will these colour-prints differ. Therefore these prints cannot be
looked upon as mechanically accurate copies of colour, any more than
photographs are absolute in their renderings of the values of a
picture. But by increasing the difficulties the margin of variation
increases also. Nor can these prints often claim to be objects of
beauty in themselves. Their shiny surface, their tendency to lilac
tones irrespective of the original, and the blur of the screen, all go
to prevent them being as decorative as a fine photograph.

Mr. Bale quotes the opinions of various artists who approve these
reproductions of Turner, which he wishes to be regarded as a
counterblast to my criticism. It would be indecorous to contend
against such an array of Pontifical *ex-cathedra* declarations, begin-
ning with those of the President of the Royal Academy and ending
with the President of the Royal Society of Painters in Water-
Colours. I will, in this case, only quote from Mr. Bale's letter and
say: "This is not a question of opinion but of fact."

The last authority whose opinion is quoted—Sir Ernest Waterlow
—makes an interesting statement: "To the busy man who has little
time to visit Galleries the work will prove a boon, and will, I am
sure, be highly appreciated." What possibilities are opened up to
future hard-worked Presidents! No longer will they have to visit
the Galleries of Europe to become acquainted with the works of the
great masters. In future, in the intervals between painting a
masterpiece and of presiding over a business meeting of "members,"
distinguished heads of Royal institutions will consult pocket editions,
in three-colour process, of the works of great men of the past and
present. It will no longer be necessary to waste time on foreign
journeys, for the glories of Madrid and Venice will be produced
"neatly bound in boards," and on very shiny paper. By means of a
row of volumes the busy artist will possess the museums of Europe.
Mr. Clausen goes even further, and says: "One can turn to the
book again and again, as one can to the fine originals. . . .
Indeed, the reproductions are as good as the drawings." Happy
Mr. Clausen, who now possesses the treasures of Turner at the mode-
rate cost of three guineas, and is as content with these prints as
with the treasures of the National Gallery. I can only say, in con-
clusion, that I envy Mr. Clausen.
H. S.

A FEATURE in the report of the proceedings of the sixteenth annual
meeting of the U.S. Association of Economic Entomologists is an
address on insect photography by Mr. M. V. Slingerland. While
urging the importance of this comparatively new application of photo-
graphy, the author points out that many of the replicas of photographs
published in current literature are of a very inferior type.

MARK TWAIN gives the following account of his first meeting with
the late Mr. Whistler. "I was introduced to Mr. Whistler in his
studio in London. I had heard that the painter was incorrigible
joker and was determined to get the better of him if possible. So
at once I put on my most hopelessly stupid air and drew near his
canvas. 'That ain't too bad,' I said, 'only here in this corner,' making
as if to rub out a cloud effect, 'I'd do away with that durn' cloud.'
'Be careful, sir!' cried the painter, 'don't you see the paint is not
dry?' 'Oh, that don't matter,' said I, 'I've got an old pair of
gloves on.' We got on well after that."

WARM TONES ON BROMIDE PAPER.

Dr. Lakin's formulae as reported in "The Photographic Record" (organ of the Manchester Amateur Photographic Society).

For warm tones directly by development the developer invariably used is Pinakol P. (amido-acetate of soda plus pyro), a developer which merely requires the addition of water, and is very receptive to the restraining action of potassium bromide, 10 per cent. The formula: Pinakol P., 2 drms.; potassium bromide (10 per cent.), 30 drops; water, 6 oz. If the time of exposure is doubled, then with this formula we get a fine sepia colour; with a still further increase of exposure and the addition of more bromide, we can get a fine range of colours ending in a pleasing red chalk. With a metol-hydroquinone made as follows we can get red or brown tones:—Stock metol-hydroquinone developer: Metol, 50 grs.; hydroquinone, 15 grs.; soda sulphite, 500 grs.; potass. bromide, 10 grs.; potass. carbonate, 100 grs.; water 20 oz. Developer for colours: Metol-hydroquinone (stock), 2 oz.; water, 20 oz.; citric acid ($\frac{3}{4}$ per cent. sol.), 1 oz. Ten times the exposure required for black tones will give a brown tone, and if we allow the developer to stand four or five hours before use we obtain with the same exposure red tones. The addition of ordinary table salt (80 grains to $\frac{3}{4}$ oz. of edinol developer) will, with a slight increase of exposure, give us fine brown tones. A toning formula which gives fine sepia tones is: A. Ammonium molybdate, 65 grs.; glacial acetic acid, 4 oz.; water, 10 oz. B. Potassium ferricyanide, 45 grs.; glacial acetic acid, 1 oz.; water, 10 oz. For sepia tones: A, 2 oz.; B, $2\frac{1}{2}$ oz. For reddish brown, equal parts of A and B. Prints must be thoroughly fixed and washed before toning, and again washed after toning. This formula is practically the cheapest toning bath for bromides, with the exception of hypo and alum, and gives very fine sepia tones.

Commercial & Legal Intelligence

NOTICE of Removal.—We learn that Messrs. L. Trapp and Co., dealers in photographic materials, late of 29, Budge Row, E.C., have moved their offices and showrooms to Milton House, 8 and 9, Chiswell Street, London, E.C.

Mr. HERBERT ANDREW CROMARTIE WARMINGTON, F.S.I., has been made a partner in the firm of Messrs. Glasier and Sons, No. 7, St. James's Street. Mr. Warmington is a son of Mr. C. M. Warmington, K.C., and he was educated privately and at the Royal Agricultural College, where he was successful in gaining the first place in the examination for membership in August, 1895. He was afterwards articled with the well-known firm of Messrs. Chinnock, Galsworthy, and Chinnock, and in 1901 he won the Crawford Prize at the examination of the Surveyors' Institution. The style of the firm will remain the same.

WORLD'S Advertising Company, Limited.—The above-named company has been registered with a capital of £25,000 in £1 shares. Object, to adopt agreements: (1) with J. Rosenberg, J. Wertheim, and J. Wenk, trading as the World's Advertising Company; and (2) with J. Rosenberg, J. Wertheim, J. Wenk, and W. Gibbons, and to carry on the business of general advertising contractors, agents, and displayers of advertisements of all kinds by magic lantern, cinematograph, biograph, or other device, etc. Minimum cash subscription, 100 shares. The first directors are W. Gibbons, J. Wenk, and J. Wertheim (all permanent). Qualification, £250. Remuneration as fixed by the Company. Registered office, 34 and 35, High Holborn, W.C.

HAND-COLOURED Local Views.—A specialty of Mr. Philip G. Hunt, 100, Deansgate, Manchester, are local views in plain collotype, platinum printing, and hand-coloured; and his staff of operators is constantly taking new series in all parts of the country to suit customers' requirements, while he also does a large trade in reproducing from clients' own negatives. He has the sole agency for Great Britain for Messrs. Deyhle and Wagner, of Berlin and Paris, and supplies also real photo postcards, hand-coloured, of high-class quality and beautifully finished. We may mention that for the convenience of London publishers he is shortly opening a London office, where samples and full particulars can be obtained.

FORTHCOMING EXHIBITIONS.

June-October.—Glasgow Photographic Exhibition. Secretary, Gallery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Secret. W. Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee Hall, Andover.

September 16 to November 5.—Photographic Salon, Dudley Gall. Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secret. E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Fortieth Exhibition, New Gallery, Regent Street, London. Secret. A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. sec., H. Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 3.—Frome M.I. Photographic Society. Hon. Secret. B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec. James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secret. Walter Seife, 70, Paragon Road, Hackney, London, N.E.

November 21-26.—Sheffield Photographic Society. Joint Secret. J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 65, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec. G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secret. F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-1 West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. Kimber, Oakdene, Highfield, Southampton.

December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secret. W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 25, Bank Street, Hillhead, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. Issott, 62, Compton Road, Harehills. Leeds.

FORTHCOMING COMPETITIONS.

June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

June 30.—Kodak. £1,000 in cash prizes for pictures taken on Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 16.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugman, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £50 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

We have been asked to announce that our contemporary, "Focus," will issue its "Birthday" number next week. Extra pictorial literary, and other matter will be included to mark the celebration of the completion of the paper's first year of existence.

New Apparatus, &c.

Beck Steinheil Unofocal Lens. Sold by Messrs. R. and J. Beck, Ltd., 68, Cornhill, London, E.C.

A new Unofocal lens invented by Dr. Rudolph Steinheil, of Munich, and manufactured under his patent by Messrs. R. and J. Beck, Ltd., has some novel optical properties. It consists of two component lenses, two of which are positive and two negative, and the result of these component lenses is that they have all the same focal length, and, moreover, are all made from glass with the same mean refractive index. Such a construction would suggest that an exact neutralisation was produced by the two positive against the two negative component lenses, but the power is obtained by placing the lenses at slight distances apart. It is well known that whereas a convex lens of one inch focus will exactly neutralise a concave lens of the same focal length when they are placed in contact; it will no longer do so when the lenses are separated. For the same reason two lenses with different dispersion but the same mean refraction may be made use of to correct the chromatic aberration. It may, however, be wondered for what reason this undoubtedly ingenious method of constructing a corrected lens has advantages. It may be here explained in order to make an anastigmat lens, a certain condition, called the Petzval condition, has to be satisfied. This condition demands that the foci of the component positive or convex lenses of an

anastigmat lens must bear a particular ratio to that of the component positive or concave lenses, and this ratio has to be that of the inverse indices of the glasses out of which the lenses are made. The utmost possible differences in this respect between the lenses which the available is very small—about 15 to 16—so that positive and negative lenses have to be very nearly the same focus. Consequently they have to be individually very high in the center, deep concave lenses balanced against deep thick convex lenses, and the result is a balancing of great errors of a positive lens against equally great negative errors. In order to properly correct all the corrections in a photographic lens, when hampered by a serious limitation, is very great, and Dr. Steinheil's new method of making all the foci and the refractive index of all the component lenses the same removes this difficulty, and allows the designer of the foci and the shapes of the lenses to be determined in a way as to correct all the other errors. The Petzval condition has long been, as it were, automatically complied with, long focus power lenses may be employed, which allow of flat curves, which produce scarcely any loss of light from reflection, and consequently increase the relative rapidity. The Unofocal lens is free from flare, and a $f/4.5$ lens when stopped down is as good as any other for wide angle work. The central definition is so good that it is suitable for telephoto work and projection. The lens is made in two series, with an aperture of $f/4.5$ and the other $f/6$.

ERRATA.—In our issue of last week (the Jubilee number), will our readers kindly note the following errata:—P. 495, interpolate between two lines of Mr. Wall's article, "are made, we may feel confident that they will be recorded in the." P. 497, col. 1, line 34, for "Snowdon and Ward" read "Snowdon Ward"; col. 2, line 4, for "Dr. Hill Norris" read "Dr. Hill Norris"; line 6, for "Joyce" read "Joyce"; line 23, for "Trail, Taylor" read "Traill Taylor"; line 24, for "Sutton-Rylander" read "Sutton, Rejlander"; line 25, for "Lake, Glacier" read "Lake Price, Glashier." P. 509, col. 1 line 12, "Davanne" read "Davanne"; line 14, for "fakings" read "dings."

Meetings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held June 9, 1904, Mr. R. Becket in the chair.—Mr. W. T. Wilkinson gave a lecture on "Factorial Development," in the course of which he pointed out that from the first appearance of the image it is possible, by the aid of a suitable factor, to prognosticate the exact time the image will require for complete development, the density being controlled by modification of the constituents of the developer. Even the purely mechanical time (or machine) development is a scientific and workable method—e.g., a normal developer, a standard subject, and correct exposure all lead to a stated time for the full effect of development. Take the case of copying a set of diagrams by artificial light. Better and more uniform results can be obtained by timing the development than by trusting to visual examination during the process. For studio work also, where the conditions are mostly normal and the exposures almost uniform, time development is practical and useful. For general outdoor work, however, this time development cannot be applied. It would not be possible to develop in the same dish a plate exposed upon an open landscape and one exposed in a dark crypt—that is, of course, if both negatives are wanted to be good; therefore, for general work, we must use the factorial method of development, and control the results by suitable modification of the developer, to suit the subject, plate, and exposure. With factorial development, for correct exposure, the time of first appearance is very regular, and when that time is exceeded or advanced prompt measures can be taken to remedy the error. The developer should be compounded to suit the subject, also the particular kind of plate used, slow, medium, rapid, and extra rapid—each requires its particular strength of developer. Slow plates, being prone to hardness, must have the reducer in less quantity than the medium plates; whilst rapid and extra rapid plates require the presence of a restrainer. All these factors must be taken into consideration, as well as the development factor of the particular reducer used. With factorial development and controlled developer a far greater proportion of good results are obtainable than by the older hit-or-miss style of judging the result. Factorial development is the only possible method for scientific work, such as three-colour negatives, microphotography, etc. By the use of time development (factor controlled) intensification and reduction are seldom required. It is invaluable to the beginner and a help to the expert. Development itself is only one of the many stages between the glass plate and packet of gelatine to finished negative, and time plays an important part in all these stages. Time has a great influence on the sensitiveness of the film during coating and drying, and quite as great upon its exposure to light; therefore it is the height of absurdity to deny that a time factor is not applicable to what may be called the last, but not the least, stage in the making of a negative.

The discussion was opened by Mr. Rapson, who took exception to the statement that studio exposures were uniform, as he had found the light fluctuate very much during the day. Mr. Rapson preferred to use time development for three-colour negatives on account of the dim light necessarily used, making it almost impossible to see the first appearance of image. Mr. Thomas asked why could not an exposure on an open landscape and a crypt be developed in the same dish if both had received the proper exposure. Mr. Pennett said that all negatives must be developed to suit the printing process, and that could only be done by

a suitable modification of the developer. A flat landscape would have a ratio of contrasts, probably 1 to 10; the crypt 1 to 500 or 600. When the exposure is made the photographer should decide what sort of a negative is required, and developer mixed according. Personal experience will tell how far to go; time should not enter into the question at all. He had tried all methods, and the diagrams shown were the results of own measurements, confirmed by independent testimony. Mr. Thomas could not see why both time and factorial development should be condemned, and said that probably the truth lay somewhere in between the opposed method.

The London and Provincial Photographic Association will have an outing to St. Paul's Cray Common, Chislehurst, on Saturday, June 25, and a supper at the Bickley Hotel, near Chislehurst Station. Reserved accommodation will be provided on the train leaving Cannon Street Station at 2.20 p.m., and on the return train leaving Chislehurst at 10.6 p.m. The supper will be served at the Bickley Hotel at 7.30 p.m., Mr. Oscar Hardee, photographer, Chislehurst, presiding; Mr. R. J. Kindon, hon. secretary, occupying the vice chair. Members and friends should apply for tickets (price 5s. 6d., including return railway fare and supper) as early as possible, so that adequate arrangements may be made, both for comfortable travel and efficient catering at supper. Tickets are obtainable from Mr. W. T. Wilkinson, 226, Malpas Road, S.E.

CROYDON CAMERA CLUB.

JUNE 1.—An ingenious and inexpensive little device recently introduced by Messrs. Houghton for daylight development was shown by Mr. E. A. Salt at an informal meeting, the spring session having closed. In form it presents a flat rectangular case of transparent ruby celluloid, open at the top to allow of the plate's insertion, which is effected under cover of a portable changing-bag, the aperture at the same time being covered with a close-fitting lid. One wall of the case is recessed, to allow free access of the solutions to the sensitive surface of the plate. The developer is fed in through a pipe, which extends up one side of the case, and a tap allows the developer being withdrawn, and the plate washed and fixed. A plate was successfully developed and fixed without any apparent difficulty, although some misguided amusement was shown at the operator's omission to turn off the tap at the start, and thereby receiving a considerable proportion of the developer up his sleeve. He stated he had no previous experience with the appliance, which appeared a trifle obvious. Mr. Dunmore somewhat pointedly asked if a discussion would be permitted. Mr. Salt removed his coat and said, "Certainly." The former speaker then changed the subject, and produced a series of negatives on plates all taken from one box, which were covered with minute spots shining with the lustre of gold; he wanted to know the cause. The President, Mr. S. H. Wratten, said he had never seen anything of the sort before, but had little doubt the spots arose from particles of some foreign matter settling on the film.

News and Notes.

We have been informed that the publication of the "Optical Lantern and Cinematograph Journal" will be suspended till October next.

PHOTOGRAPHIC CLUB.—At an adjourned meeting of the committee on June 8, it was decided to call a special general meeting of the members at 8 p.m. on Wednesday, 22nd inst., to receive a report of the committee with regard to the present position of the club, and to adopt such measures as may be deemed advisable in its interests.

SINCE the publication of our Jubilee number we have been in receipt of numerous excellent suggestions re the B.J. Encyclopædia. We have decided to take advantage of some of these, the inclusion of which will necessarily delay the appearance of the introductory chapters. A further announcement regarding the work will therefore be made in a future issue.

The Savage Club.—In recognition of his services to the Savage Club as hon. secretary and "as a mark of friendship and esteem," Mr.

E. E. Peacock was presented on Saturday night with an illuminated address and a silver bowl, together with a diamond bracelet for his wife, and a cheque representing the balance of a subscription from 300 members. A handsome clock was also presented to Mr. Peacock by the staff of the club.

NATURE STUDY.—A nature study museum has been opened at George's recreation-ground, adjoining St. George's Church, Southwark. The museum, which is a branch of the Stepney Borough Museum, and is under the direction of the Public Libraries Committee, has been established for the exhibition of simple and common forms of life, with the hope that it may be used by the schools of the district, as well as by the public. It is intended to arrange short courses of lectures on the various forms of life shown.

THE ROYAL PHOTOGRAPHIC SOCIETY.—A technical meeting was held at 66, Russell Square, W.C., on Tuesday, June 28, 1906, at 8 p.m., "On Instruments for Sensitometric Investigations, with Historical Résumé," by C. E. K. Mees and S. E. Sheppard. Synoptic Coating machines; a new machine for accurately coating plates in small quantities. Exposure instruments: an enclosed instrument the Hurter wheel, with a standard acetylene light; a device thermostat for the control of temperature during development. Photometers: the Hüfner spectrophotometer and some new fittings for the measurement of plates.

OPEN SPACES IN SURREY.—On the summit of Colley Hill, Reigate, on Saturday last, a large undulating stretch of land, which had been presented to the borough by Mr. George Taylor, of the well-known firm of A. and G. Taylor, in memory of Queen Victoria, was formally opened as a park by Viscount Middleton in the presence of several thousands of the inhabitants. Viscount Middleton said that several favoured spots should be rescued from the builder. There were over six hundred different tracts of common or village greens within Surrey, and there was no other county in England of the size of Surrey which possessed so many open spaces for the public.

SALISBURY CAMERA CLUB.—A Camera Club has been formed in Salisbury and district, and a provisional committee has been elected to make the necessary arrangements. It is suggested to hold meetings in the winter for discussions, demonstrations, exhibition of lantern slides and prints, and other matters of interest. Photographic outings will be held during the summer months. Various photographic papers will be taken, and circulated amongst the members. Any persons interested in photography, and desiring further particulars, are requested to communicate with Mr. C. Osmond, honorary secretary, pro. tem., "Glenthorne," London Road, Salisbury.

DEATH OF MR. W. J. ROUTLEDGE.—The photographic societies of the north have suffered a sad loss by the demise of Mr. W. J. Routledge, who died suddenly whilst at his business on the 7th inst. The deceased was hon. secretary to the Gateshead Camera Club, and also acted as one of their delegates on the Council of the Northumberland and Durham Federation. Well known as a lecturer and demonstrator amongst the local societies, and being tactful and genial, he made many friends, and his services were always at their disposal. He was personally attracted towards the pictorial side of photography, and his work more than once received awards.

THE HULL PHOTOGRAPHIC SOCIETY visited Newbald and Houghton Woods last Saturday afternoon. The church claimed most attention from the fact that it is a fine specimen of Norman architecture, and an excellent state of preservation. The doorways, font, and beautiful arches were much admired, as well as photographed. The outing of this society have been, we understand, remarkably well attended, due, no doubt, to the determined effort on the part of the officers of the society to make each item on the syllabus both profitable photographically and socially, and so far this has been warmly appreciated by the members. The next outing, to Burton Constable, on June 25, will be in the nature of a picnic. Arrangements are being made, which include permission to the grounds of the Hall.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on the 6th inst., his Grace the Duke of Northumberland, K.G., president, in the chair. Mr. Richard Bagot, Mr. W. Carrington, Mr. E. G. Fellows, Mr. W. R. Freeman, Mr. R. F. Nicholson, and the Hon. C. A. Parsons, F.R.S., were

members. The sincere thanks of the members were returned to Andrew Carnegie, who is so intimately associated with the steel industries, for his donation of £1,200, to enable Mr. Dewar and Mr. R. A. Hadfield to prosecute their joint investigation on the physical property of steel and other alloys at various temperatures, and to Dr. Frank McClean for his donation of £100 to the research fund of the Royal Institution.

A radium clock, which will keep time indefinitely, is the latest invention. The principle of this apparatus is simplicity itself, the rate of time being made in two-minute beats, whilst its function is to exhibit the dissipation of negatively-charged alpha rays by radium. The clock comprises a small tube, in which is placed a minute quantity of radium supported in an exhausted glass vessel by a quartz rod. To the lower end of the tube, which is coloured violet by the action of the radium, an electroscope formed of long leaves or strips of silver is attached. A charge of electricity in which there are no beta rays is transmitted through the activity of the radium into the leaves, and the latter thereby vibrate until they touch the sides of the vessel, connected to earth plates, which instantly conduct the electric charge, and the leaves come together. This simple operation is repeated incessantly every minute until the radium is exhausted, which in this instance would occupy thirty thousand years.

At the Counter.—One often hears curious things asked for over the counter, but the photographic dealer surely gets more curious queries than most trades. "Houghton's Monthly" tells us:—The day a pretty girl came into the shop and asked for some photographic paper, and seemed quite upset because a tube of ordinary photographic paper was given her. She said she particularly wanted the tube that she had asked for, because it had such a pretty name. The dealer was sure other dealers stocked it if they didn't. Then he remembered, too, of a case where a man came in and returned a photograph, saying that the lens was faulty because the image on the photographic screen was upside down. He said that he thought at first it was merely due to accident, and imagined that the lens had been fitted wrongly; yet he had tried to screw the lens in differently many a long time, but had not succeeded in getting the picture right way up. Could he have another lens? It took a good half-hour to explain that the lens and the camera were all right, and then he went out of the shop with the feeling that he had been deceived somehow.

Scottish Photographic Federation Excursion.—The first annual excursion of associates of the Scottish Photographic Federation, was held on Saturday last, when a representative assembly gathered from all parts of the kingdom. The arrangements were under the care of a small committee, consisting of Messrs. Munro (convener), Coates, and Baird, who were assisted in their task by Provost of Callander, and Mr. Arch. Menzies; the Provost unfortunately was unable to be present owing to illness. On arrival the party was photographed in the immediate neighbourhood of Callander. Then, with Ben Ledi, the bridge, and many fine tree studies; then to Roman Camp and Bracklinn Falls. After lunch in the Dreadnought Hotel, Blair's coaches took the party a delightful drive—witnessing scenes for photography—via Pass and Falls of Leno to Loch Lomond, where the inevitable group was taken, then via Kilmahog, to Gortchionzie Bridge to Loch Ness, and returning by Coilachalan Woods in time for tea. The whole outing—the weather was all that could be desired—was a very enjoyable—good fellowship prevailed, and there was much humorous stalling of better-known associates—and augured well for the success of future outings.

SYNOPSIS.—As the name implies, this is a new method of obtaining printed impressions from animal or vegetable life. The Journal of the Society of Arts for June 10 gives the following description of the process:—The subject to be reproduced is placed on a sheet of paper and pressure is applied; this leaves a hidden impression on the paper—strong or light, according to the amount of oil or moisture contained in the subject. This design is developed by the aid of a coloured powder, which is dusted over the impression; this brings the complete print into view in a permanent colour. If necessary, the impression can be made to remain undeveloped for a considerable time—three months have

elapsed between printing and developing some of the work done by the inventor. The process is specially adapted for finger printing, as it is no longer necessary to blacken the fingers with pigments. Pending the publication of the inventor's patent specification, full details cannot be published, but it may be stated that prints can be made on any ordinary paper, though the best results are obtained on the paper prepared for the purpose. The whole process is a speedy one, and takes less than a minute to make an impression and develop the print.

PHOTOGRAPHS of Old Pictures.—An association has been formed under the name of the Arundel Club, for the purpose of preserving and publishing records of precious works of art in private collections and elsewhere. The prospectus states that:—"All German and most American Universities are engaged in forming collections of photographs of all kinds of works of art of the past, from the days of ancient Egypt down to the Nineteenth Century. It is only in England that no such collection has been undertaken." A correspondent of the "Morning Post" takes exception to this statement, and says that it "argues a singular ignorance of the subject on the part of those responsible," and he points to the collection of photographs in the Victoria and Albert Museum. Sir Martin Conway writes in reply:—"As one who has often used that collection I venture to repel this accusation. The museum collection doubtless contains a great number of photographs, but it makes no attempt at historical completeness, as it is not primarily a historical collection at all. One such collection I know of in England, and one only. In it the attempt has been made to arrange the photographs in strictly chronological and geographical order from the earliest prehistoric epoch down to modern times. Between a collection thus arranged and a mere assemblage of photographs in boxes under the names of the artists to whom the original pictures are often wrongly ascribed, there is a difference not merely of degree, but of kind." Any persons interested in the undertaking should address the Hon. Secretary of the Arundel Club, Mr. Robert Ross, 10, Sheffield Gardens, Kensington.

ART and Literature.—Mr. Edmund Gosse, at the anniversary festival dinner of the Artists' Benevolent Fund, said that among the young art critics who ruled opinion at the present day—a race whom they admired and feared—no opinion was more fiercely or more scornfully repudiated than that there was any relation between literature and art. If they timidly reminded them that this was not the view of Hazlitt and Haydon, or, in later days, of Ruskin and Leighton, they proudly answered, "So much the worse for your Leightons and your Hazlitts." He would not deny that there had been occasions, and still might be, when art and literature had hung too languidly in one another's arms. He need but remind them of a flagrant example. During our late African misunderstanding there was produced a picture which professed to portray Lord Roberts in his tent, holding a baby Boer upon his knee, and teaching that sympathetic little fugitive to spell out its Bible, while his own orderly stamped with impatience at the door of the tent. That was a ridiculous work, in which they might almost say that art held open the trap while literature poured liquid sentiment down the sewer-pipe. But such examples—and others less flagrant than that—did not make him consent to that complete divorce between the painted and the written word which our latest critics desired. When Keats, some ninety years ago, was writing "Endymion," he saw the great Titian, the "Bacchus and Ariadne," which was now one of the glories of our National Gallery. It had then lately been brought to England. His imagination was completely inflamed by what he saw, and he went home to interpolate into the fourth book of his poem that magnificent passage about the noise of revellers that came over the light blue hills, which was in verse nothing else than what Titian's composition was in colour. He thought that this mutual relation between poetry and pictorial art was one which must be preserved, in spite of the abuse it had received from cheap and incompetent hands. It was right that art should pursue its own course, with complete intellectual independence; but it was to go too far, it was to limit the scope of its pre-occupation with beauty, to refuse to allow it to be influenced by poetic images and even by philosophical ideas.

"SRIHIT Photographs."—The claim that a sensitive plate on occasion will reproduce images of things that no human intelligence could detect in front of the camera, and that such images represent

materialised "spirit forms," is an egregiously impudent one. I would remind my readers of the remark of an old and experienced photographer, who said, when discussing this subject, "You can never be sure what a plate will develop." Dr. Russell's experiments on photography in the dark proved that sensitive plates wrapped in freshly printed newspapers would receive impressions from the paper without exposure. Let us suppose such a plate to receive the image of a face from an engraving, and to be afterwards used and developed in the ordinary way, and one may easily see how a perfectly natural phenomenon might be construed in terms of the supernatural. I can give another case in point. A lady during an illness was shocked by being shown a photograph, developed from a snapshot, in which she was depicted with a procession of nuns passing her by. The camera had not been used by her, and no recollection of a conventual scene was possible of being recalled. She had been snapshotted by a friend, but the nuns' procession appeared to her somewhat in the light of a disagreeable portent. The explanation came in the shape of a previous exposure of the plate in Italy. The procession was duly photographed, but a second exposure of the plate in her case resulted in her appearance in the somewhat mystical scene. It is in much the same way that you can have taken a photograph of yourself as you exist in the solid flesh, while alongside of you another self appears, ghostly and transparent, so that your friends can see through you perfectly. As for the spirit-photographers, they are simply tricksters all. Mankind, because of their savage origins, may never be able wholly to free themselves from the influence of superstition appearing as a factor which exercises an influence on their life and fortunes. He is the happy man who, discarding the idea of luck altogether, works while it is called the day, and determines that he alone is "captain of his soul."—KAY, in "The Referee."

BRITISH Exhibits at St. Louis.—In the department of chemistry (classed as a group in the Liberal Arts) Great Britain makes an excellent show on both the theoretical and the practical sides. In manufacturing chemistry so much notice has been bestowed on the triumphs achieved in Germany by synthetical carbon-chemistry, in the manufacture of artificial indigo and numberless other dyeing materials and in the production of new pharmaceutical preparations, that the public is in danger of forgetting that, after all, these carbon-compounds occupy only a small part of the whole field of chemical industry, and that apart from them there is a host of substances the importance of which is none the smaller because they have been known and used for a much longer time. This fact is illustrated by a wide range of British products exhibited in this section—phosphorus, sulphur, arsenic, bichromates, copperas, alum, cyanides, and all the varied products of the acid and alkali manufactures, not to mention pure drugs and pharmaceutical preparations. The exhibition, too, serves as a reminder that in pure research Great Britain has taken no insignificant part, and that in one particular branch at least she still retains the predominance won more than a century ago. "La Chimie," Wurtz declared, "est une science française." When one thinks of the names of Boyle, Black, Cavendish, Priestley, Davy, and Faraday, it may be said with greater truth that the chemistry of gases has been a British science, and the British exhibits at St. Louis suggest that, in spite of notable contributions by workers in other countries, such it still remains. During the last decade five new gases have been added to the list of those contained in the atmosphere, and this addition has been made by the joint efforts of two British men of science, Lord Rayleigh and Sir William Ramsay, the latter of whom shows specimens of the new substances. During the same period Professor Dewar has completed in the laboratories of the Royal Institution the work which was begun in the same laboratories by Davy and Faraday a century ago, and has reduced to the liquid and solid state all the "permanent" gases of the older chemists. One of the most striking exhibits at St. Louis is a reproduction, on an even larger scale than the original, of the apparatus used by Professor Dewar for the liquefaction of hydrogen. This apparatus has been constructed to the order of the Royal Commission from designs by him, and it is to be shown in operation at frequent intervals during the course of the exhibition. Further, in connection with this exhibit a series of lectures is to be given by Mr. J. E. Petavel on the scientific work carried out on the subject from the time of Faraday down to the present, and for this purpose a large quantity of apparatus, together with diagrams and lantern slides, has been sent over.

Correspondence.

THE "B.J." JUBILEE NUMBER.

To the Editors.

Gentlemen,—As to the Special, it is really worthy of the old paper and does you as great credit as it must give you satisfaction. I was struck with were the portraits of some, whose names are familiar but who one has not met personally. Really, I should like to have a paper give us a collection of those who, in various phases of photographic work, one knows by repute, a kind of "Who is Who." It seems so different to what one had pictured.—With all good wishes and all congratulations, faithfully yours,
 W. THOMAS

2, Tanfield Court, Temple, E.C.

June 10th, 1904.

To the Editors.

Gentlemen,—I feel I must just send you a few lines congratulating you upon your Jubilee Number. It has given me the greatest pleasure to peruse its pictures and reading matter, and must have spelt "Well" with a very big "W." in its preparation. It will be prized, I am sure, as a pleasing souvenir and a valuable record of fifty years' progress in the photographic world, in addition to the interesting details of birth and fifty years' growth of your influential journal by the photographers of the world. Again my congratulations and best wishes for another fifty years' success to the "B.J."—Believe me, sincerely yours,
 NEWMAN, MAYALL AND CO.

91, King's Road, Brighton.

June 10, 1904.

From amongst a large number of congratulatory letters on the subject of the Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY that we have received we select the following extracts:—

"Congratulations on its bulk and interest."—GEO. E. BROWN, F.I.C.S.S. (London.)

"Permit me to congratulate you on your Jubilee issue. It ought to have the effect of increasing your output."—EDWARD DUNMUR (Southend).

"Congratulations on your Jubilee number."—RAINES AND CO. (Ealing).

"Having dabbled in photography for over forty-six years, I can well understand my appreciation. I congratulate you heartily for the most interesting reading I have had lately."—JOHN WHITEHEAD (Scarborough).

"Congratulations from an interested reader."—J. K. HOME CROFT (Portobello).

"Your Jubilee number is a brilliant idea, and is surely worthy of an extension. So many of the early fathers still have a memory amongst us, and no doubt you have many other portraits you can include in future numbers, even if only one or two a week."—ARCHER CLARKE (London).

THE DETENTION OF SPECIMENS.

To the Editors.

Gentlemen,—I notice in the last issue of your journal a complaint from one signing himself "Poor Assistant." I shall be glad to mingle my tears with his. I have replied to over a hundred advertisements, and also enclosed eighty-six stamps, without receiving a reply. I on one occasion sent the whole of my specimens as original testimonials, with sufficient stamps and properly re-addressed with boards for their safe return. That was some four months ago and yet they have not returned. I admit being fool enough not to keep the number and letter of the advertiser (he giving no name or address, for reasons best known to himself), but, of course, I thought I was at least dealing with an honourable person. The non-return of specimens or stamps to me was a puzzle, but on reading in your journal the article giving the information that they are teaching photography to the criminals in gaol, and successfully, I can quite understand my stamps and specimens never being acknowledged.

ned. I think if you would insert the above in your journal it be the means of at least an acknowledgment on the part of stamp collectors.—Believe me, sincerely yours,

ANOTHER POOR ASSISTANT.

To the Editors.

Gentlemen,—I notice this week a letter from an assistant coming of the treatment of himself by employers. I am of the opinion, as I now have my specimens in the hands of an entirely high-class photographer who has neglected to return whether wilfully or not, of course, I cannot tell. I have written requesting their return, but no notice has been given. I intend sending the gentleman (?) the price of postage in stamps, as perhaps he has had so many to return he is unable to affix a penny stamp. At any rate, few assistants have so many specimens that they can afford to lose what they have. I am of the opinion that it would not be a bad plan for every assistant whose specimens are detained beyond a week to expose the name of the employer in the JOURNAL for the benefit of other poor victims.—Yours faithfully,

A LADY OPERATOR.

The following notice appears in the advertisement pages of every number of the JOURNAL:—"** In applying for Situations where specimens are sent, it is preferable that they should be unmounted. In every case, the owner's name and address should appear on the back of each photograph, which would avoid confusion and facilitate return. Postage for return of specimens should always be enclosed." Much regret that we cannot devote further space to the discussion of a subject which so frequently crops up in our columns.—B.J.P.]

NOTE ON THE RESORCIN HYDROKINONE DEVELOPER.

To the Editors.

Gentlemen,—In April, 1901, I read, before the Croydon Camera Club, a paper, which was reprinted in the BRITISH JOURNAL OF PHOTOGRAPHY, April 26th, 1901. In that paper was given a formula for a developer which contained both Resorcin and hydrokinone, and which I at the time believed the Resorcin to play an important part. When I took up the study of development in 1902 with Mr. Sheppard, Mr. Sheppard told me that he considered the Resorcin in that formula to be utterly useless. At that time I had no opportunity for investigating the question, but I have recently worked the matter out in the following way: Two plates were exposed in a camera, so as to get a graduated series of known exposures. The first was then prepared without Resorcin, and one plate was developed for 30 mins. at 20 deg. C. in the developer without Resorcin. The correct quantity of Resorcin was then added to another portion of the developer, and the second plate was developed for the same time in this portion. On measuring the developed densities and plotting the results it was found that the addition of the Resorcin had greatly weakened the developer; in fact, the velocity of the development had been divided by four by the addition of the Resorcin. The cause of this weakening is fairly obvious; the Resorcin has no developing power of its own, but all the same it requires a considerable quantity of the hydrokinone, which would otherwise be available for the hydrokinone. I thus found that the Resorcin, so far from being an advantage, actually weakens a hydroquinone developer, nothing remains but for me to apologise to any whom I may have misled. I believe that the Resorcin was very little used, but it is certainly desirable that so great an error should be pointed out as soon as possible.

C. E. KENNETH MEES.

THE MEDAL QUESTION.

To the Editors.

Gentlemen,—The following figures, which represent accurately my own experiences as a consistent contributor to most of the exhibitions of the last season, may provide food for reflection to those who are interested in the medal and pot-hunting question. I have entered for fifty-one exhibitions this season, receiving fifty-one awards. These awards have been won by fourteen different persons. The cost of exhibiting has been as follows, viz.:—Entrance fees, £10 14s.; carriage, £8 2s.; repairing broken frames,

glass, etc., £4 11s.; framing bill, £36 19s. 2d.; photographic material £12 3s.; total, £72 9s. 2d.

This is a very serious bill for one exhibition season, but to set against that there is on the credit side the amount of £62 5s. received for the sale of pictures, and the medals themselves, leaving a net cost of £10 4s. 2d. It is just a little over twelve months since I first entered an open class at an exhibition; therefore, sir, you will understand what an amount of hard work it has involved and of scores of nights in the dark room and of the week-ends of printing, as practically the whole of this work has been done apart from the ordinary hours of business. I have long ago come to the conclusion that a thing that is worth doing at all is worth doing well, and it seems to me, sir, that if there was a little more enthusiasm and a keener desire to work amongst amateurs as a whole there would be less grumbling about pot-hunting, as they would become medal winners themselves.—I am, sir, yours, etc.,

ARTHUR MARSHALL.

King Street, Nottingham, June 9, 1904.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—What I will tell you here is not much of photography, but since you speak of psychic photography it may well find its place here, and as the following writings may not be well put down for printing in your BRITISH JOURNAL OF PHOTOGRAPHY, nor, perhaps, prove interesting to your readers, I will leave it entirely to you and your responsibility to publish it or not or write it down again yourself in a clearer or more satisfactory way, hoping you will understand what I mean and I am perhaps unable to explain well. After reading this you will probably take me for a heretic, but I cannot very well imagine the hereafter of a soul, and therefore nothing that can be photographed except pure imagination, which is shown by the dressing of the psychic photos, which is purely conventional, and as one imagines it to be, or should be, from former-seen engravings, modern or old costumes, and principally draped bed sheets. We have learned from childhood that nothing down here is eternal, and even radium, which is said to be so, has shown by calculations not to be so entirely, however incalculable years are thought to be necessary for its disappearance, yet not immortal, and then why should the soul be so, and be able to come back and be photographed? Another puzzle has always been to me to know at what age this soul comes back or shows itself to mediums. We have heard—at least I have read—of spirits of children which, having died as infants or below ten years of age, returning ten years later (these years more or less), at the age of twenty, with all the knowledge attached to that age and taught at school. How is that? Then we have parties that died at the age of forty always showing themselves at that age; these do not change or grow older. Why? Then we have spirits of people that died at seventy, and possibly eighty or more, that died from age and in infancy, or maybe lunatics. Do these show themselves through mediums or in bed-sheets or any other way as they were born, or at eighty in infancy both sides, or at what age and cured by magic at twenty, thirty, forty, or what?

Now, here is what would rather be my idea of what souls are made of and how their disappearance (and possibly later on their reappearance, if it is ever to be so) may be explained. Everything that is on this earth exists there and remains there. Nothing is added to it nor leaves it on account of the immense vacuum that exists around it. All that is on earth may suffer transfiguration and change-form, but does not disappear. Trees grow, make ashes, or decay, and from this other trees grow. Animals are born, die, and leave place to others, and even feed on each other. Why should not the souls act in the same way. To-day, in the reign of electricity, we find it everywhere and nowhere. Supposing that the soul is formed of something analogous which is itself found everywhere, but a fluid as yet unknown, and some explanation may be formed of why it should be there with more or less energy or knowledge in man, and yet completely disappear after the death of the body or battery that contained the mysterious fluid and stored it until it broke. Now, we have a baby that is born. It is a total void. It cries, but does it hear? It has eyes, but does not see. Feelings are very dull, if present. But it has a battery called brains, which is ready to receive all kinds of impressions. These impressions, which will form his mind and soul, are all around in the world, and ready to assimilate themselves with the matter ready to receive them, and in proportion

to the development of each cell which is in each brain. Something like the anteurs, which are now ready to receive the new wireless telegraphic messages and retain it. To help this assimilation and storage we have first mother and father, then the professors, etc. Later on sickness may rob a party of some of its faculties so acquired, and at last, when death arrives, the whole resolves again in the air to be acquired again by a new battery. This would explain why some parties are more ready to receive impressions than others, development of one thing to the detriment of others, and why some whose receptacle is defectuous will never be able to understand or acquire one thing or the other. But this would be pretty much the end of psychic photo, or return in one body of a separated soul, except something else happens and another explanation. Maybe a medium will be able some day to reconstitute the particles disappeared at death, but then, how can we reconstitute the body to the photographer? There is the mystery.

I give you the above idea for what it is worth. Do with it what you please. It does not mean that there is no God, but tries an explanation of things existing.—Yours very truly,
A. LEVY.
Asnières (Seine), June 4, 1904.

To the Editors.

Gentlemen,—It is to be regretted that your correspondent, Mr. D. Bachrach, should have so hastily assumed fraud in the photographs which he examined because a few of them presented the appearance of screen work. The majority do not, and therefore should have suggested careful inquiry as to the why and wherefore of the difference.

Claïrovoyants have occasionally during certain sittings described to me that the spirit sitters were behind a kind of auric veil or netting, the mesh of which varied in size with the individual. Mr. B.'s own experiences of twenty-five years ago, for which, of course, he expects full credence, should have made him more considerate towards others who obtain abnormal results on their plates. His testimony is, however, very welcome, as it may stimulate others to find out that everything must not be put down to halation, fog, etc.

A lady of my acquaintance, strongly mediumistic, has been the despair of several photographers, who have been quite unable to take a good normal portrait of her owing to curious lights always appearing.

Considering that photographs or representations of spirit faces, designs, and other markings have frequently been obtained in total darkness, both with and without the use of a camera, it is futile to argue, as does Mr. N. Maskelyne, that the photographs must be fraudulent because some of them are not according to what the usual laws of photography would lead us to expect as to lighting, etc.

Though I have made a close examination of many of those Mr. Maskelyne refers to, I have not been able to find any in which the aura is of a woven texture.

In full materialisation this is the case, and on several occasions the spirit visitors have, by request, cut off small pieces of their spirit drapery, some of which has afterwards slowly dematerialised, while others have remained.

Replying to another point, I have many spirit portraits of those who lived prior to the photographic era, but they do not differ in any way from the modern ones.

The spirit workers can, however, through the means of a suitable medium, reproduce the appearance of an engraving or picture should they so desire, and seeing that it is reported that we can by the aid of electricity do the same at the other end of the wire, it would not be so surprising if they could do likewise by a kind of wireless telegraphy.

We should also remember that nearly 20 years ago Mr. A. R. Chatwood succeeded in reproducing on a sensitive plate the image of a piece of printed paper at which he had steadily stared for a considerable time, and the spirit workers, with their more extended powers, may be able to do this with the quickness of thought.

Mr. Maskelyne most conveniently leaves out of his reckoning the evidence of various clairvoyants who have repeatedly seen the spirit visitors taking up, and sometimes altering, their positions by the side of the sitter, and also that in very many cases the spirit friends have in this way fulfilled promises made by them, in some cases thousands of miles away.

Had the duplicate rabbit marks referred to been produced by double exposure, the prints would naturally have been carefully cut down.

One explanation of these has been suggested by Mr. Levy in letter.

In the United States there are two or three photographic mediums who obtain spirit faces when copying a photograph.

In my own case I am surrounded by fourteen faces, and five of them have been previously taken with me in a different pose in London and Washington. The photographer is a complete stranger to me, has taken over 1,300 during the last few years; they are all different and each showing a number of faces. I trust that now the question is being so thoroughly ventilated, we shall hear of others in country who may develop this phase of mediumship, and that will have the courage to come forward and further prove that spirit photography is a fact.—Yours faithfully,
H. BLACKWELL.

June 13, 1904.

P.S.—In your report of the discussion which followed the reading of my paper on the above subject, your reporter has unintentionally misquoted some of my replies. With your permission I will correct in your next issue.

To the Editors.

Gentlemen,—There is much that can be said upon spiritual manifestations that you, I take it, could not admit into the "B.J." Therefore, I will endeavour—difficult though it be—to confine my remarks to its photographic phase. I attended the meeting of the London and Provincial Photographic Association, at which Mr. Blackwell lectured. I took a camera and plates, hoping that perhaps I might get a chance shot or two at the spirits. But I understand, from Blackwell's reply to my query, that my camera would have to be magnetised before I could succeed, so I did not try. Perhaps some day I may reach a higher astral plane (I think that is the proper term) and be able to magnetise my own apparatus; meantime, it seems to me that a good business could be done in ready magnetised cameras and plates, if only Mr. Blackwell would put one of our large medium or dealers in the proper way of going about it, otherwise I fear there is little chance of the ordinary or garden photographer ever attaining to the higher ranks of the cult. As the case stands, one has to have his camera magnetised, employ a medium (they make a charge—naturally), and expose a large number of plates and yet get no spirit photograph whatever. One is apt to get tired of this negative result, and cease to persevere. I cannot imagine anything less calculated to remove that wall of prejudice with which we are said to be surrounded and which is such an insuperable barrier to our progress.

It was not till after the meeting was over and we had left that I knew we had had a clairvoyant, who was also a clairaudient, as we the whole evening, and he told me that our old friend, Traill Taylor was standing between Mr. Henderson and myself, laughing at Henderson's remarks. I cannot help regretting that this opportunity of communing with him was lost to me, an opportunity that probably will never occur again. I think he should have spoken at the time. I also had some very serious talk with a member of the London Provincial, who has gone into the matter a great deal. Among other things, he told me that everybody could become a medium. It is a mere question of striving to be one, believing in it, and persevering while to others it comes as a gift. This is only reasonable, for do not know that while some of us are born, say fools, others only grow so. Moreover, he advised me to have nothing to do with spirits, as he knew of so many cases where nothing but disaster followed. He tells me that good spirits are not permitted to appear to mortals; it is only the evil ones who do so, and they take delight in deceiving, annoying, and punishing those who meddle with them. This is a great comfort to me, and probably explains why I have not succeeded in my wish to communicate with the departed. I take it that those I wished to communicate with are too good to get leave to come. To those who wish to try psychic photography, I may add, I elicited from Mr. Blackwell that the exposure for a spirit "ranged from a snap-shot to one minute," but as most of the slides shown that even represented a human being besides the spirit, no matter whether it was in the nebulous form or materialised, it would appear that you must have to trouble yourself about the correct exposure for the mortal, spirit adjusts itself to this. For myself, at least for the present, I think I shall take my friend's advice and leave spirits alone.

Walthamstow.

ALF. J. BROWN.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., Wellington-street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Dean, 14, High Street, Rugby. Photograph of Men Leaving British-Thomson Austin Co. Works, Rugby.
Burton & Sons, 8, Haymarket, Leicester. Three Photographs of the Last Sir-day head in the Humberstone Gate, Leicester, May 16, 1904.
Kime, 116, St. James' Street, Newport, I. W. Photograph of Second Sherwood Foresters' Football Team 1903-1904.
Tate, Main Street, Westford. Photograph of The Most Rev. Dr. Browne, Lord Bishop of Ferns.
H. Gardiner, Daneway, near Cirencester. Photograph of the Church of St. Melinus, Sapperton. Photograph of Daneway Wharf, Thames and Severn Canal.
Cock, 35, Longbridge Road, Barking, Essex. Photograph of the late Rev. J. McDonald.
Kilks, Exchange Street, Retford, Notts. Two Photographs of Mr. F. Newman.
Don Photographs of the Rt. Hon. Sir F. Milner Bart., M.P.
Tattersall, 55, Avenue Parade, Acclington. Three Photographs of Opening Ambulance Drill Hall, Acclington.
S & Nixon, 200, Bank Street, Alexandria, N.B. Photograph of the Rev. W. Blachier.
Hence, The Station, Station Road, Dunbar. Photograph of Highland Cattle.

WORKING REGISTERED:—

Horton, Wansford House, Sunny Hill, Halton, near Leeds. Drawing of the H. P. "Advertising Curtain.

REF.—We know nothing of the matter, and cannot help you in it.

ADOLPHUS.—Your query, as you say, in no way relates to photography, and we are sorry we cannot help you. We might suggest, however, that you consult a dealer in art metal works. He might be able to restore the bronze statue for you.

PLAT-TINS.—"PLAT-TINS" asks: "What can be done with these? Will any one give anything for them?" In reply: Unless the Platinotype Companies will, we do not know of any one else who would. In future, please write on a sheet of paper instead of a post-card.

MOND.—If you will carefully read the Rev. T. Perkins' article again, you will see that the price mentioned does not include the cost of the block, which, as the author says, will be about half a guinea extra. This brings the price up to those you quote.

GMATIC.—It is quite without our province to criticise what appears in the pages of a contemporary, or to pass any opinion upon it. It is certainly not our intention to adopt the suggestion you make. Your best way will be to study the works of the best artists, and emulate them. The prints sent are tolerably good.

TRAVELLER.—"TRAVELLER" asks: "Will you kindly pass your opinion upon enclosed prints? These were taken by Field Camera, with R.R. Lens; 1 and 2 were taken in a room; 3, 4, and 5 were taken outside. These have not been picked, but are from my ordinary work. What class should they pass under?" In reply: To be candid with you, it is very poor work, say, third or fourth rate.

INQUIRY.—"I shall be much obliged if you will kindly give me your opinion of my retouching. I have enclosed a few prints, taken both before and after retouching. The negatives from which they are taken are not very good, but the only ones to hand." In reply: The work is but fairly good. Much of the modelling in the faces has been destroyed in the retouching.

A LEGAL QUERY.—FREE PHOTO SYSTEM asks: "Could I post the enclosed warning up in my shop window, also insert it in our local paper, without making myself liable to law?" In reply: We should think you could; but before doing so we think you should consult your solicitor. If you are a member of the Professional Photographers' Association it will assist you in the matter.

COPYRIGHT QUERY.—REPRO says: "Would you give me your opinion upon the following case? I photograph a professional gentleman, present him with a dozen copies, and register the photograph copyright. He then purchases from me a dozen copies. 1. Does that purchase destroy my right to possession of the negative and the copyright? 2. Has he the option of giving permission to reproduce?" In reply: 1. No; certainly not. 2. No; the copyright is yours, not his.

WOODEN DISHES.—ARTEMUS asks: "Is it practicable for me to make dishes of wood, say about 25 in. by 21 in., for fixing and washing bromide enlargements in? If so, what should I caulk the joints with to make watertight? and should the whole inner surface of the dish be also covered with any preparation? If so, what?" In reply: Yes. If you are a good carpenter the joints will not require caulking. The inside should be coated with some impervious-to-water material, such as pitch mixed with a little tallow or paraffin wax.

COPYRIGHT QUERY.—"F. E. G." asks: "Will you kindly say if registering photographs as follows is in order? A gentleman was invited to sit for his portrait, and after some difficulty he agreed, and in due course a print was sent to him; meantime, registration forms were obtained, but on same day as this was sent to Stationers' Hall, I received an order for a number of copies. Would this invalidate the registration?" In reply: If the portrait was taken at your solicitation, and was not paid for by the sitter, the order for copies will not invalidate the copyright.

EMPLOYMENT WANTED.—"B. B." says: "On the other sheet of paper I give you my qualifications. I am anxious to procure a berth with some firm or private gentleman not in the ordinary photographic business, and I think your advice would be of great help. If you would kindly give me your opinion how I might possibly get such a berth. I have thought of trying to get in some observatory, if they employ photography." In reply: The only suggestion we can offer is that you advertise your qualifications and requirements in the advertisement columns of the JOURNAL.

MOUNTING.—"MOUNTANT" asks: "Would you kindly let me know what is the best mountant for sepia platinotypes, when they have to be mounted on a very thin mount? I have tried starch and flour, and even kept them under pressure after mounting, but they buckle when dry, and will not keep their flatness for any length of time. I shall be glad if you will help me in the matter." In reply: The best system of mounting in these circumstances is that of the Dry Mounting Company, Fetter Lane. E.C. They will mount the prints for you. The mountant given on page 1,071 of the "Almanac" is a good one for the purpose.

COPYRIGHT QUERIES.—"COGNITO" asks: "Would you be good enough to answer the following questions? (1) Would it be an infringement to copy a picture which had been made copyright, but was not so marked? (2) Assuming that the answer to question (1) is as follows: 'Yes; it is an infringement,' what legal steps could the holder of the copyright take in the case of an infringement? (3) Is it absolutely necessary that a copyright picture should be marked 'copyright'?" In reply: (1) Certainly it would. (2) Sue for penalties (not exceeding ten pounds per copy), damages, an injunction to restrain the production of further copies, and the forfeiture of all prints, negatives, etc. (3) Not at all.

CELLULOID.—IGNORANT asks: "1. Of what is celluloid composed? 2. What is its cheapest form, and its cost? 3. What are its cheapest solvents and their cost? 4. Also, I have some old views of local buildings (long since demolished) not taken by me. Should I be right, legally, in offering them to a firm of postcard publishers? Some I have copied and possess the negatives, others only prints. I know the pictures have not

been copyrighted in any way. I shall be very pleased to know your opinion." In reply: 1. Nitro-cellulose and camphor. 2. The price depends upon the quality. Better get the price from the makers. 3. Probably acetone. From about 1s. a pound. 4. Yes, if there is no copyright in them.

WATER RATE.—"WATER" writes: "I should be very much obliged if you will kindly help me by answering the following. When chance permits I do professional work, portraits, etc. I have just had some cards printed and circulated. I have no studio, and do not use a great quantity of water. To-day I have received a water rate demand note for 2s. 6d. for one quarter. (1) Am I obliged to pay this in addition to the usual one of 7s. 7d. per quarter? (2) If so, is 2s. 6d. the correct charge? I might mention this is a private house." In reply: (1) If you use the water for trade purposes, as apparently you do, you will be charged extra for it. (2) Each water company have their special rates, and the extra rate charged to you seems to us very moderate.

DEVELOPER.—"COB" asks: "Would you kindly inform me (1) which self-toning paper you consider best suited for proofs? I prefer dark chocolate colour, or near it, if possible. (2) Also, of a good developer for bringing out detail in white dresses, etc. I should prefer to use dry pyro, if possible. Or a formula for pyro soda, for using dry pyro. (2) How could I obtain several prints as specimens of good posing and lighting?" In reply: (1) It is, as we are continually saying, against our rules to recommend any particular maker's goods. (2) Any developer will answer if it be used somewhat diluted. (3) We should say that the best way would be to purchase some of the portraits of celebrities, taken by the best photographers, as shown in the shop windows, and study them.

STUDIO BLINDS.—E. WEST says he should be glad of advice on the following: "I have a small studio, 18 ft. long, 9 ft. wide, 6 ft. to eaves, 9 ft. from floor to ridge. Can you advise me the best way, and material for blinds, to light same to get best results? Have drawn rough sketch below. There is 8 ft. of glass, as shown, 1 ft. from background end." In reply: As the aspect of the studio is not stated, it is not really possible to say what is the best colour to use for the blinds. If the studio is lighted from the north, light blue blinds would be suitable. If from the south, then a dark green would be preferable. Curtains would be best for the sides, and blinds for the roof. It is a pity that the 8 ft. of glass was not placed more in the middle of the building, say, commencing 4 ft. or a little more from the background end.

MOUNTING GLOSSY PRINTS.—"MOUNTANT" writes: "On page 451 of the BRITISH JOURNAL you recommend treating glossy P.O.P. to a formalin bath before squeegeeing on to the ferro-type plate, saying that after becoming dry the prints may be dipped in water, and mounted in the usual way. By adopting this treatment, could any starch paste be used for mounting (I use Higgins' at present) without injuring the glossy surface, or is a special gelatine mountant required? If so, would you kindly give particulars of same?" In reply: If you read the article again you will see that we did not recommend the method. It was extracted from an American journal, to whom we credited the suggestion. Personally, we have not tried the method, but we have little doubt that it is all that is claimed for it. The mountant you are using, we should say, would answer quite well.

FLASHLIGHT COPYING.—G. BELASCO says: "Kindly give me the following information, as I am very fond of photographing old carvings, either portable, or as fixtures. I wish to photo some very old and beautiful oak (black) wainscot and overmantel work, but situated in a very dark hall, where little or no light penetrates, and to accomplish this critically, I wish to know the following items of interest: (1) the lens; (2) the stop; (3) time of exposure; (4) the plate; (5) whether ribbon, or dust magnesium as a flash, in fact, just what you would do yourself; (6) if ribbon, what length, if powder, how many flashes repeated (single), and in what position the light to shine on the work?" In reply: (1) Any lens that will cover the size plate you require. (2) The largest that will yield good definition all over the plate. (3) That will depend upon

the intensity of the light. (4) Any ordinary plate of med rapidity. (5) Ribbon would perhaps be the better. (6) This is quite a matter of judgment, and as we do not know subjects, we can give no opinion. Why not employ daylight? The subjects will not move, and any length of exposure may be given.

COPYRIGHT INFRINGEMENT.—X. Y. Z. writes: "I am sending you paper and pictorial postcard. The stationer who issued the card had permission from me to reproduce photograph (of which I have copyright) on condition my name and word 'copyright' be printed. The newspaper has pirated the same, and completely ignored me. I would not have troubled you in this matter, as I have consulted a solicitor, but after reading often in your valuable journal the advantages of the Copyright Act, I was surprised at his (the solicitor's) advice, which was to take no further action, although he admits I have a claim and would receive damages, which, in his opinion, would exceed £5. He also informs me they could prove that it in no way hurt the sale of my photographs, and in that case might only be awarded a farthing damages. Even at best would make no more than pay expenses. What I should like to know, should I ask a sum of money to prevent it going to court, and, if so, what would be a reasonable amount to ask, and in the event of them not complying would you advise me to proceed farther?" In reply: Legally, you have cause of action if the case be as stated in your letter. But as you have consulted your solicitor we should say you should act on his advice, which seems to us perfectly sound, particularly as the newspaper has since explained in its columns that the copyright is yours. Your solicitor might, possibly, obtain a small sum from the paper, which they would perhaps pay to avoid litigation. This query is further dealt with in another column.

SIGHT Tests in the Mercantile Marine.—The report of the sight tests in the Mercantile Marine for the year ended December 31, 1903, has been issued as a Parliamentary paper [Cd. 2,111]. It states, in three tables, the details of each case of failure reported, the percentage of failure in form vision and in colour vision to the total number examined, and the nature of the defect in each case of reported colour blindness. The number of candidates of competency as officers in the Mercantile Marine and others who were reported to the Board of Trade as having failed to pass the form vision, colour vision, or colour ignorance tests last year was 40—19, or a percentage of 0.47 out of 4,641 candidates, having failed in form vision, and 21, or percentage of 0.45 out of 4,622 candidates, having failed in colour vision. Among the failures in colour vision there were four cases of complete red blindness, or 19.0 per cent. of the total number of failures, and .09 per cent. of the total number examined for colour vision; two cases of incomplete red blindness, or 9.5 per cent. of the total number of failures, and 0.4 per cent. of the total number examined for colour vision; nine cases of complete green blindness, or 42.9 per cent. of the total number of failures, and .19 per cent. of the total number examined for colour vision; and six cases of incomplete green blindness, or 28.6 per cent. of the total number of failures, and .13 per cent. of the total number examined for colour vision. Appended to the report is a chart of specimen colours of the various series of skeins used in the examinations.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL JUBILEE NUMBER.

Special Jubilee Number of THE BRITISH JOURNAL OF PHOTOGRAPHY, which we published on Friday, June 10, met, we are pleased to say, with a most cordial and favourable reception at the hands of the photographic public—indeed, the success achieved was so striking and instantaneous as to cause even ourselves, who had anticipated the Special Number would secure a wide degree of appreciation, the liveliest feelings of gratification and assure at the chorus of commendatory approval meted out to the issue.

Several extra thousands of the Special Jubilee Number have been printed, and they are selling rapidly at the ordinary price of twopence per copy, or by post twopence-halfpenny. The number consists of a total of 132 pages, and forms the largest ordinary issue of any photographic journal ever published in the United Kingdom. The contents include thirty special articles by the foremost photographic authorities of the time; a history of THE BRITISH JOURNAL OF PHOTOGRAPHY since its foundation; and about twenty original portraits of celebrities connected with photography; thus forming a unique and most interesting souvenir of the Jubilee of the oldest photographic journal in the world.

As this souvenir number of the JOURNAL is in such demand, and is shortly likely to be scarce, readers at home and abroad who have not yet secured a copy are advised to do so without delay.

EX CATHEDRA.

Still Another Property of Radium Discovered.

When shall we know all that radium will do, or what it will not do? Every week—almost every day—brings forth some new discovery of its most remarkable properties. Last week Sir Wm. Crookes, at the Royal Society, communicated some curious observations illustrating the effect of radium emanations on the diamond. It appears that when a crystal is exposed to the impact of radiant matter it becomes phosphorescent of different hues, and assumes a dark colour. After a long exposure it becomes almost black, though the time for that varies with different stones. This coloration seems to be due to the formation of a coating of graphite—a form or carbon—on the gem. Sir William said he had also found that by a different method of applying the radiant matter the colour of the diamond was altered without the formation of a crust, which was suggestive of a chemical as well as a physical change. By this treatment it was suggested that it may be possible to improve the value of gems by deepening the colours of those which are but slightly tinted. Should the above method of treatment of precious stones turn out to be practicable in a commercial sense, we imagine that some of the dealers in gems will not be slow to take advantage of it, because we all know that the value of gems is greatly dependent upon their tints or colours. If these can be changed from those of comparatively little value to those of greater worth, even if the cost of doing it is great, it may prove remunerative, particularly with gems of the larger sizes.

* * *

Interesting to Hand Camera Workers.

Hand camera workers, who used to delight in snap-shooting the vessels and barges moored in the lower Thames, much regretted the suspension of the penny steamboat service. The boats now plying between Westminster and Greenwich every twenty minutes throughout the day gives them the opportunity of continuing their work, which they have been unable to do for the past season through the withdrawal of the boats. Vessels of all sizes group well, and at all times make, with suitable lighting, good pictures. The dismal looking tug, vomiting forth dense masses of black smoke, followed by a string of heavily-laden barges, with a background of wharfs, usually makes an excellent picture. In the docks, too, no end of fine pictures are to be obtained, either with a hand or a stand camera. When taking the annual holiday at the seaside London amateurs rarely fail to embrace the opportunity, and it is a little surprising that they seem to quite ignore the shipping on the Thames, which is available to them all the year round. Now that the boats are again running, there will be ample work for the hand camera on the lower Thames—between London Bridge and Greenwich. The vessels of all

nationalities moored in the Pool and in the docks make excellent subjects for hand camera work, and may well be obtained from the steamboats. Indeed, a dozen, or a couple of dozen, plates may be profitably exposed going and returning, between London Bridge and Greenwich, any fine afternoon—Saturday or any other. Of course, in making the exposure from a moving boat it must be brief. Therefore a quick shutter, rapid lens, and highly sensitive plates should be employed if sharp pictures are desired. With these there is no difficulty in obtaining excellent results from the river steamboats now running.

* * *

The Art Season.

Those who glance through the advertisement columns of the daily press need not be reminded that the picture season is now "full swing." The Royal Academy and all the other annual shows are open, as well as some additional ones. For example, at Earl's Court there is an exhibition of Italian pictures that are well worth seeing, and, recently, a loan exhibition of Irish pictures was formally opened at the Guildhall Art Gallery by the Lord Mayor, accompanied by the Lady Mayoress and the Sheriffs. The pictures shown, it should be mentioned, are by Irish artists, as there cannot be said that there is an Irish school in art in the sense that there is a Dutch school, a Flemish school, an Italian, or a French or English school. The pictures shown are, however, by Irish painters, and amongst them are some very fine works by the best masters, though perhaps not their very best pictures. There are works by MacIise, Mulready, Shannon, Brabazon, Hayes, Asborne, Lavery, and many others. The pictures that will probably attract the greatest attention by the general public are those by Mulready, by reason of their vivid colouring and exquisite drawing. Amongst this artist's work is the "Choosing the Wedding Gown." This picture, it may be remembered, was the one selected for the Society of Arts competition some few years ago, for the substantial prizes offered by it for the best photograph plate, untouched, from a picture. If at any future time there should be a competition for a good size reproduction of a painting in colours by means of photography, we cannot call to mind a better subject for it than this picture. Anent art makers, it may be mentioned that at a sale of pictures at Christie's on Saturday last, some very high, if not record, prices were realised. For instance, a Gainsborough, a portrait, fetched 3,300 guineas; a Reynolds, also a portrait, made 4,000 guineas; while a Turner, "Walton Bridges," was knocked down to a firm of picture dealers (Messrs. Agnew and Sons) for no less a sum than 7,000 guineas. The total amount realised at this one day sale was between fifty-eight and fifty-nine thousand pounds.

* * *

Sight Testing.

The Spectacle Makers' Company is one of the few old City companies that are taking really active measures in the furtherance of the crafts they are supposed to represent. One day last week the first of the examinations in sight testing as instituted by this Company was opened. Over a hundred opticians were present, candidates for the award of a diploma attesting their skill in the correction of defects of vision. In some introductory remarks, the Master of the Company, Mr. Alban G. H. Gibbs, M.P., referred to the fact that the practice of sight testing by opticians had been challenged from an influential quarter, but said that the various issues had been carefully sifted and weighed by a committee, and it was decided that sight testing should be recognised by the institution of a special examination of opticians engaged in the trade. He added that, at the expressed wish of the trade, and very properly

too, he thought, they had obtained first-rate professional co-operation. He trusted that in future the position of an examiner to the Spectacle Makers' Company would be looked upon by ophthalmic surgeons as a highly privileged one, offering, as it did, great opportunities and responsibilities for promoting a proper understanding of the limits their practice should not overstep. All we think will commend the Spectacle Makers' Company for the step they have taken. Good eye-sight is one of the greatest blessings a person can possess, though it is too often impaired by those who vend spectacles, and who do not understand their business by selling glasses that are thoroughly unsuited to the vision of the purchaser. If he finds—as is too often the case—a pair of spectacles that he can see a little better with than his old ones, he makes the purchase—possibly to the injury of his eyes. But if he purchases from an optician who holds a diploma from the Spectacle Makers' Company, he has the satisfaction of knowing that he is getting what is best for his sight, even if he has to pay a little higher price than he would do at the ordinary spectacle vendors. It is not every one who can afford to pay the fees of an ophthalmic surgeon when he finds his eye-sight failing him. Hence he has had recourse to the ordinary vendor of spectacles, with the result that his vision has suffered to the end.

* * *

A Meteorological Discovery. Photographers, like most other persons, have been at a loss to discover a reason for the excessive rainfall of the past two years. The business depends largely upon fine weather, and they naturally feel that if the cause of unusual moisture could be ascertained, there might be some remote chance of a remedy being found for the evil. Meteorologists have failed to give a satisfactory explanation of the phenomenon, and beyond a few vague references to the Gulf Stream and spots on the sun, have nothing at all to say upon the subject. But at last we have a ray of hope. It comes from a remote place known as Fraserburgh, in Scotland, and we have the more faith in it because we know that the inhabitants of our northern counties are shrewd about ordinary mortals, and are not likely to be carried away by silly rumours. The good people of Fraserburgh have traced the rain to the wiles of Marconi. To reduce the matter to plain language, it seems that under the auspices of the Italian inventor, a wireless telegraphic station has been completed at Fraserburgh, and that, according to the local report, "since the erection of the shaft here a day has passed without a heavy rainfall, particularly during the hours of experimenting, and the inhabitants of the district have come to regard the presence of the station with suspicion." The people at Poldhu, in Cornwall, have followed suit, and have gone so far as to petition to have the wireless apparatus removed. Anyone who has had experience of Cornish weather for a few decades will smile at the idea that wireless telegraphy or anything else could possibly make it more moist. But this is no digression. Signor Marconi does not smile at the idea; he laughs outright, and says: "If anyone can prove that I am spoiling the English weather, I shall have great pleasure in dropping my work in this country, and sending my instruments to Australia or Egypt, where rain is very much wanted." Still, we must confess our sympathy with the people at Fraserburgh and at Poldhu. It is so satisfactory when a grievance exists to find some one who one can put "on toast." Hitherto we have had no one upon whom we can wreak our vengeance when bad weather sets in. We, some of us, went so far as to call the weather "beastly," or "abominable," or "wretched," and we have known some who have, under stress of irritation, un-

stronger language than that. But we have always felt want of some one who could be made to suffer personally for the loss and inconvenience brought about by inclement weather, and if Signor Marconi is brought forward to fill this gap in our midst he will add to the debt of gratitude which we already owe him for his wonderful inventions.

* * *

Origin of Cine-Photography. A few weeks ago there was some discussion in our columns as to the genesis of the cinematograph, and we had occasion to refer to a very early contrivance for projecting different pictures of a picture upon the lantern screen for the purpose of giving the idea of motion. We have since that time discovered in a book, which bears date 1744, a copperplate engraving which is so ingeniously drawn, that two separate episodes in one story are contained therein, and must credit the artist with thus forestalling, by nearly a century and a half, the idea of the "living picture." For quite evident that the same genius which prompted the artist to represent two phases of a movement would have been capable of suggesting any greater number, and possibly the labour of engraving the metal plate alone stopped his hand. The volume referred to is "The New History of the Bible," by the Rev. Thomas Stackhouse, published in London at the date already given, and the particular picture referred to is illustrative of the story of Jonah. At the right-hand side of the composition there is represented a town of some importance with a marine parade in front, and a sea with extremely curly breakers. In the far distance is a ship with its one sail flying up in the breeze, and having a good time generally. This, of course, is the vessel with Jonah on board when they started for their sea trip before the crew found out what a bad cargo he was. A mile nearer the ship is shown with the sail down, and a villainous black cloud overhead, which is fringed with straight lines, which indicate rain. A still nearer view is once more given of the vessel, and this is large enough for us to distinguish the men on board who seem to be engaged in once more turning up the sheet—for they have got rid of the inclement prophet. There is the old gentleman struggling in the water with the huge fish, which seems to be a cross between the conventional sea-serpent and a gigantic periwinkle, about to swallow him. This monster of the deep is once more shown in the foreground—indeed, it is quite the principal object in the picture. It has its mouth wide open, for it has just ejected Jonah, who looks not at all the worse for his uncomfortable experience in the interior of seaside lodgings. It will thus be seen that we have in this masterly design all the elements for a cinematograph picture, the ship being shown three times, and Jonah and his host twice. So that we must give the Rev. Thomas Stackhouse, who was Vicar of Beenham, in Berkshire, the credit of being the first cinematographer. At the same time we are somewhat puzzled to know why this learned clergyman undertook the compilation of this extraordinary book, which runs to two folio volumes, each of about hundred pages. Probably it consists of the sermons preached by the author, for it partakes of the character of the old-fashioned discourse, in that it gives biblical stories in reconstructed sentences. Mr. Stackhouse does not improve upon "that well of English undefiled" when he says: "the Fish disembogued itself of Jonah" on the eastern shores of the Mediterranean Sea. But one cannot wish that he had been on the spot when the prophet was so summarily ejected from his moist quarters, and that it had been possible for him to have employed a cinematographic camera.

Reconstitution of the Meteorological Office Advised.

On Thursday last week the Committee appointed by the Treasury minute of a year or two ago to inquire and report as to the administration by the Meteorological Council of the existing Parliamentary grant, and as to whether any changes are desirable, presented their conclusions. The general public knows the work of the office chiefly through the forecasts of the weather for the next twenty-four hours as they appear in the newspapers daily. No body of persons, perhaps, except agriculturists, fishermen, and the like, are more interested in the weather we are to expect for the next day or two than are photographers—that is, those who are engaged in outdoor work. We have more than once alluded to the unreliability of the forecasts as at present issued by the Meteorological Office, to which an annual grant of between fifteen and sixteen thousand pounds is made. The report issued by the Committee shows that for the decade ending 1902 the percentage of complete successes were 55.7 and partial successes 27.3. This is certainly not a high percentage when it is considered that in settled weather, when the barometer is high and steady, and perhaps rising, it is not difficult for anyone to forecast fine weather for the next day, and it is in such circumstances that the Meteorological Office has scored many of its successes in their reports. It may not be known to the general public that the Meteorological Council is neither a Government Department nor a private concern. It is, in fact, an association incorporated under the Companies Act. The members are directors of it, appointed by the Royal Society. Nevertheless, it receives and administers the grant from Parliament of the sum just stated. It may be mentioned that the Council was formed in 1867 to take over the work of a department in the Board of Trade after the death of Admiral Fitzroy. The Committee that has just issued its report suggests that the registration of the office as a company under the Joint-stock Companies Acts should be cancelled, that it should be wound up, and the office reconstituted as a department under the control of the Board of Agriculture and Fisheries, to whom the present grant would be transferred. The necessity for a Council of seven having been thus got rid of, they recommend that the office be placed under the control of a man of science as Director of Meteorology, appointed after consultation with the Royal Society, but responsible to the Board of Agriculture and Fisheries, and making his annual report to that department. The Committee also make other recommendations in matters of detail which we need not here refer to. The chief one is, as just mentioned, that the Meteorological Office should be placed under the control of the Board of Agriculture and Fisheries, the bodies most immediately concerned in the weather, and not left to what is practically a joint-stock company receiving a Government grant of some sixteen thousand pounds a year. If the Committee's recommendations are adopted it is to be hoped that there will be an improvement in the reliability of the daily forecasts of the weather on those now issued. They would then be of great use to agriculturists, fishermen—and to photographers, especially outdoor workers.

WE understand that at the forthcoming Newbury Photographic Exhibition there will be a special class with first and second prizes of a guinea and half a guinea respectively for pictorial postcards. The number of amateurs who print their own cards is increasing so rapidly that the competition should prove most popular. The conditions are that all cards sent in shall become the property of the exhibition, and shall reach the hon. secretary, Mr. E. J. Forster, Guildhall Club, Newbury, not later than September 1. No entry form or fee being required.

THE DEVELOPMENT OF FILMS.

THE republication of some of the pages of our JOURNAL of fifty years ago has aroused a great deal of interest, and very considerable wonderment that photography half a century ago had achieved so much, was capable of so much. Instantaneous photographs, photographs of the moon, negatives of large size, taken in the field with all the appalling impedimenta incidental to wet-plate work, when each plate had to be prepared on the spot, and the actual cleaning of the glass to receive the sensitive coating required considerable experience to avoid spots and stains of all kinds, while the modern fripping had its analogue in the slipping and loosening of the film. All these were done—and well done—half a century ago, as in the best of dry-plate work of the present day. But in one direction a vast step has been taken. The wildest dream of the old votaries of the “black art”—an almost meaningless term to the modern camerist—a flexible glass, as celluloid may justly be termed, has been realised in the introduction of the everyday spool that can be bought for a shilling—little more than the bare cost of the glass of the collodion period. The beginning of the twentieth century has, indeed, witnessed the apotheosis of the film, with the concurrent initiation of a revolution in the practice of development. The use of long rolls of films, measured at times actually by miles, necessitated the development of thousands of exposures at one time in one solution; but this striking departure from practice was generally passed over in the marvel at the result, with little thought of its import, until quite recently. If the average photographer was certain of one thing, it was that to get a good negative it was essential to have at hand a supply of solutions of bromide and of accelerator, and would scoff at the suggestion of one solution for every exposure made. The epoch-making researches of Hurter and Driffield had literally no meaning for him, development “with the eyes shut,” as it has been termed, was a mere phantasy of the brain. An appreciation of the fact that in a general way one exposure was right, all others wrong, was slow in coming; the real value of factorial development, even with limitations, to which Mr. Watkins has brought such enthusiasm was not admitted. But now a swing of the pendulum has taken place in the opposite direction, and the you-press-the-button-and-we-do-the-rest system is extended to development. The developing machine bids fair to banish the add-a-little-bromide theory, and photographic manipulation has become still more mechanical.

There is, however, a stout phalanx of workers who still believe that every exposure needs its own development. Yet, singularly enough, in the practice of rollable film development they do not, as a rule, put their theory in practice, for, from inquiries we have made, it is the exception to treat spools of (say) a dozen exposures singly, so that, in effect, the very people who sneer at development by box adopt in their own practice a method which is virtually the same thing. We met an indignant amateur a little while ago who was loud in his denunciation of the methods of a large firm, one of whose operators he had “tipped” to permit him to see the actual development of some of his films of exposures made abroad. “He actually developed the film in lengths, gave them all the same treatment whatever the exposure. They’ll get no more films from me to be developed,” he growled. With the methods of large firms, developing films by the hundred, with the aid of every mechanical appliance possible, we are not concerned. We are writing more

particularly for the every-day photographer, who, himself or for amateur clients, has perhaps a few spools every day to treat, and who desires to get out of every exposure all its potentialities.

We find that there are still a number of photographers who cut up every spool into individual pieces and develop a number at once. It is evident that by this means there is power of making the best out of every exposure, for now we should imagine, would contend that, whether a piece has had, for example, half or double the proper exposure, the correct density, for the two placed in the developer at the same time will be obtained at the same moment; the single-piece method enables the worker to leave the film in the solution just the right length of time, and so obtain the most suitable printing capacity. All honour to those who adopt a plan which of necessity, by the mere act of cutting up and marking for identification each separate piece together with the labour of pinning them up individually, devotes attention and time which we have heretofore described as sinful. Others develop in lengths, holding the end in each hand, and passing the film backwards and forwards through the solution till suitable density is arrived at. Obviously there is no practical difference between the method and the developing machine plan, save that the latter assesses more elasticity of selection in that in case of a general over or under exposure the film can be kept in the action of the developer a greater or shorter time, as judgment dictates, and so a better general average may be obtained. The plan, too, is perhaps as economical as the other for when the film is kept in the solution by a loose roll or other method a very small quantity can be used. This mode of working the factorial system, of course, cannot be adopted. When the images begin to appear the large average of correct exposures will be chosen to calculate the time the film must remain under the action of the solution.

The third alternative is to cut the films into lengths of such size that they will go into a dish of such ordinary capacity as would be found in an average dark-room, will not involve the waste of an undue amount of liquid, say, a 12 x 10 or 15 x 12 dish. Here, with the dexterity arrived at by practice, it is surprising how many pieces of film can be developed at once, the chief difficulty being the curling up of the films in the liquid, which, as our readers are aware, is with the non-curling films more marked than with the old style, especially with spools of six, which emphasise the tendency. When they are placed in the developer after preliminary soaking in water, the curling tendency is reduced the greater the amount of the alkali employed, the pyro-soda being particularly helpful. The drawback to the plan is the liability of getting the film into kinks which are apt to produce unpleasant markings that are quite conspicuous when the film is dry.

The drying of the film is not a mere perfunctory matter. If it be suspended direct from the wash-water there is a tendency for tears of liquid to form, which make unsightly spots on finished film. A common plan is to draw the film, back and front, over the edge of the dish and so wipe off much of the water. One photographer of our acquaintance draws his films over the back of his hand. Another employs a particularly soft sponge for the purpose, while still another invariably presses the film between sheets of hard blotting paper, a plan which emphasises the drying to be more quickly carried out, the finished negatives being then very even and workmanlike in appearance. We will conclude by referring to the practice of one worker who turns his films out in a very short time. He passes every one through a weak bath of formalin made by adding about 5 per cent. of the commercial solution to water, and then blots off the superfluous moisture. It is surprising how much heat a film so treated can withstand without injury.

DISCURSIVE REMARKS ON ORTHOCHROMATIC PLATES.

II.

ate the testing of colour-sensitive plates has received considerable attention, and some very curious and contradictory results are to be met with. One pins his faith to the action grating spectrum, another to the direct vision spectrope, whilst a third believes in colour charts and natural tests, and each damns the other's method of testing and declares that his is the only orthodox method, and the others quite heterodox. Personally, I believe in all three, if the tests obtained are read correctly, and if the experiments are carried out on absolutely fair and equal lines and one does not put a bit of lead in the scale. A few discursive thoughts on the subject and a few data may lead to a somewhat more satisfactory position of affairs, or at any rate may induce some one to take into consideration that there are always two sides to a question.

The diffraction spectrum has one great advantage, and that is that the colours are more normally distributed, yet on the other hand this very advantage may mislead some to a totally erroneous idea of the results possible with a dye. Till Mr. A. K. Tallent devised his ingenious little spectroscopic camera, the number of those who had a diffraction grating camera might almost have been counted on one hand; probably now those in possession of a concave grating camera are to be numbered on one hand. The advantage of the concave grating is that it requires no lenses, there is therefore absolutely no absorption by intervening glass masses. Tallent's action camera has not only a lens but a prism, and also the alroid of which the grating is made, these must play some part in regard to absorption, but it must be a minor part, and probably only applies to the ultra violet rays, with which, at all due respect to those who say to the contrary, we have to do, when using our cameras by daylight, than they could have us believe. The direct vision spectroscope is an extremely handy little instrument, but it has two disadvantages which it is just as well we should recognise; the first is that the absorption of the ultra violet may be so great as, to use the word of an Hibernicist, to extend into the violet, where an ordinary gelatine plate is sensitive; this must of course depend upon the construction, whether it is a three or five prism arrangement and of what glass it is made. I have three direct vision prisms, which differ enormously in their results, an ordinary Browning-Grace five prism, with comparison prism and scale, which was made for visual work and is corrected for practically the D lines, another a Zeiss, corrected for G line, and a third, much the largest, also of five prisms, of which give different results, although slit aperture and focal length of spectrum are kept constant.

The disadvantage of the Tallent, or in fact any diffraction grating camera, is that the less refrangible end, the red end, of the spectrum is so spread out that sensitiveness in this region may be entirely overlooked; on the other hand, the direct vision spectroscope, this end is so humped together that a totally erroneous value is put on the sensitiveness. To put the thing somewhat baldly, if you have a crowd of five thousand people and pack them into a quarter of a square mile, they make a big impression—this is what the direct vision does—whereas if you spread the same number of people over ten square miles, then the onlooker is not struck with the existence of a crowd, and this is what the diffraction grating does. There is of course a method of comparing the two and of translating the one reading into the other and adding the scales equally between the two, but I propose at a later date to show comparative spectra taken under absolutely identical circumstances in elucidation of this point. I am a strong believer in a practical test and prefer a

colour-chart to a natural object, for the simple reason that one can measure a colour-chart and keep the measurements by one, and this is the method which the man in the street will use, because probably not one worker in a thousand has a spectroscope of any sort. But there are charts and charts. As some one once said, we do not get "spectra hanging on trees," a perfectly legitimate remark, but there is no colour in nature which is not derived from the spectrum + white or + black. The argument that a coloured chart is unscientific and useless because so much white light is reflected from the surface of such paper, no matter what its colour may be, simply shows that an unsuitable chart has been chosen. As I said before, there are charts and charts. If you happen to know a paper-maker, and can get round the right side of him, you will be able to obtain a booklet of examples of matt surface papers of all colours, which reflect very little white light at all. A lithographed chart is useless, as a rule, because the colours are not saturated; glazed papers for the same reason are not good to use. Again, there is no object in nature that does not reflect white light more or less, and the average worker does not buy commercial colour-sensitive plates to expose in a spectroscopic camera; he wants to take coloured objects and scenes with them, and therefore a practical test on a chart, if it is a good one, or a natural object, is not only perfectly legitimate, but may be scientific, because, to quote Dr. Eder, "The yellow, at the Fraunhofer line D, has been estimated by different observers as from 9 to 31 times brighter usually than the spectrum blue, at F $\frac{2}{3}$ G, and from 21 to 87 times brighter than the darker spectrum blue at G, whilst pigmentary yellow is from 6 to 14 times brighter than the blue, and spectrum yellow is from 19 to 40 times brighter than the red, between B and C, whilst with pigments it appears only from 3 to 7 times brighter," and it appears quite as scientific to test the relative ratio of the light reflected from pigments as it does to test the absolutely pure spectrum, which has no admixture of white light or black.

There is of course another important point in testing plates, and that is the light by which they are tested. I have studiously refrained, except in the above just-quoted sentence, from citing any authority, but I must be allowed to again quote Vierordt's table of the visual luminosities of different lights, and also some measurements (Eder) of the relative photographic luminosities, which support this statement and prove that by using one light or another you can put as much lead as you like in the scale and totally falsify results, if this is not taken into account.

VIERORDT'S TABLE.

	Brightness in the Spectrum.				Total Brightness in Candles.
	C.	D.	b.	F & G.	
Standard candle	73	100	104	134	1
Gaslight	74	100	103	125	16
Limelight	59	100	113	285	90
Electric light	61	100	121	735	362
Magnesium light	50	100	223	1,129	215
Moonlight	87	100	155	363	204
Sunlight	45	100	250	2,971	70,000

An examination of this table shows how enormously the different lights vary visually; C is the orange red, D yellow, b the green, and F $\frac{1}{2}$ G bright blue.

Unfortunately, I know of no comparison table of the photographic values of these lights, but Eder gives the

Amyl acetate lamp as visually 1 candle, photographically	1
Lime light	70
Gas light (Argand)	16
Magnesium	80
Electric light	2,000
	25,000—75,000

My point is that unless one knows the actual spectrum composition of the light, it is impossible to form a correct opinion of the colour sensitiveness of a plate, for, obviously, if

we use magnesium, which has the least amount of red, it would give worse results than gas light, which has the most. To carry this argument to a reductio ad absurdum, we need only test a plate by the Cooper-Hewitt mercury lamp, which has no red and very few orange rays, and a colour-sensitive plate would be as bad as an ordinary.

In testing colour-sensitive plates, there is, I think, one point too frequently overlooked, and that is to get a standard for comparison. Now this can only be got by finding an ordinary plate of the same speed or giving relative exposures for different speeds and developing to the same factor. When experimenting with new dyes, I have always been extremely careful to test for general sensitiveness, and see that the dye does not lower or increase the sensitiveness, because some may do the latter. Test spectroscopically if you can; if not, use a good colour chart or natural object; judge from negatives in preference to positives, as the one is not always an exact counterpart of the other; and if for real scientific work, then the densities must be measured.

There is one method of testing, which has been cried down, but which, when properly and scientifically carried out, is extremely valuable, and that is to test for the relative sensitiveness to yellow and to blue. In default of anything better, a Chapman-Jones plate tester may be used, but the best way is certainly that suggested by Eder. He uses a Scheiner sensitometer, which is practically a Hurter and Driffield machine, and interposes between the light and plate a cell filled first with ammonio-oxide of copper, and then with potassium chromate solution; the former transmits practically all the blue-green, blue, and violet, to which silver bromide is sensitive, that is, determines the sensitiveness of the plate if it was an ordinary one; the chromate transmits the greenish-blue, green, and yellow up to red, and determines the colour-sensitiveness of the plate, and the resulting densities are plotted out, and the speeds can be thus directly compared, having first of all determined the reduction in speed of the plate by the interposition of the cell filled with plain water. This would give users of plates some valuable knowledge, and I hope before long, if nobody else does it, to treat all plates in this way. The filters are made as follows:—

Cupric sulphate	25 g.
Liq. ammonia .880	q.s.
Distilled water to	1000 cc.
Cell thickness, 1 cm.				
Potassium chromate	40 g.
Distilled water to	1000 cc.
Cell thickness, 1 cm.				

I have carefully refrained, save in two or three instances, from quoting from authorities, my purpose having been rather to sound a warning note as to too much reliance being placed on individual spectrograms, or a series carried out under conditions which do not approximate to the conditions of everyday work. We cannot in England rely sufficiently on day or sunlight to use this for testing by means of the spectroscope, but I consider it important that for really scientific and reliable testing one or a series of spectrograms should be made by daylight, as it enables those in the know to estimate to some extent at any rate the slit width, which is important.

To those who may be desirous of taking up the subject of the study of orthochromatics generally—and there is a vast field open to those fond of experimenting—the introduction of Tallent's spectroscopic camera has considerably simplified matters, for all adjustments are made; it can be obtained with a millimetre scale; and a Bunsen burner, and three or four salts will enable the principal Fraunhofer lines to be recognised, and others can be put in by interpolation on squared paper, as described in Abney's "Colour Measurement and

Mixture." With the direct-vision spectroscope, which can, by an adapter and flange, be adapted to any camera, unless one uses a lens for projecting the spectrum and scale on to the plate, it is necessary to use a scale in contact with the plate, or scale the plate itself each time. Personally, I prefer a camera with fixed extension for this work, but allowance must be made for the blue and violet end having its focus slightly further from the plate than the red.

The main difficulty is the source of a constant light, which shall most nearly approximate to daylight; all forms of gas, whilst the most convenient, are in this respect the most unsatisfactory; magnesium is utterly unreliable; possibly acetone would be the nearest to our ideal.

One other subject, which opens up an intensely interesting and useful field of experiment with the spectroscopic camera, and which has been practically untouched, is the making of yellow screens. Using a cell of constant width, and increasing the ratio of dye to solvent, and making negatives through the same, and determining the quantity of dry dye per unit area, would give us definite data from which it would be possible to make screens having any desired absorption.

In conclusion, let me state that there is one very great difficulty in front of him who would test new dyes for their colour-sensitising properties, and that is the difficulty of obtaining the same. There is no method of knowing from the chemical composition of the dye, even if you can get at this, whether the dye is likely to be useful or not; the quantities required are extremely small; and dye manufacturers, English ones at any rate, seem to have a rooted objection to supplying gratis or for a small charge, even one gramme, but are quite willing to quote you by the pound—a quantity that would possibly sensitise every dry-plate made in England during the busiest month of the year. German firms are much kinder in this respect, and I hold many kindly letters from the same, stating that they are only too pleased to supply the small quantities required for nothing in the cause of science.

E. J. WALL, F.R.P.S.

THE Free Photo Fraud Again.—There has been a good deal of traffic in Yeovil lately in the photographic enlargement business. A firm of three men have been calling at private houses and inducing women to permit them to enlarge a favourite photograph, "absolutely free of cost." Their generosity is explained on the ground that they wish to advertise their business, and are adopting this means of doing it, trusting that the owner of the enlarged photograph will be so delighted that she will show it to all her friends. A large number of people have permitted the firm to take away photographs for enlargement. Subsequently another member of the firm calls at the house to submit specimens of moulding for the frame of the enlargement. More delighted than ever, the lady naturally chooses something to her taste, and awaits the arrival of the finished article. This turns up in due course, and the lady is charmed with it! The salesman holds it against the wall, suggests that it looks well, and finally, casually observes as he reaches the door, "The price of the frame is 25s., madam." This, we are told, has been done in very many cases in Yeovil this week. It is, of course, a well-known method, and has been described in the Press over and over again. In one case a Yeovil lady was threatened with County Court proceedings on refusing to pay for the frame, and when this threat had evaporated the man went round a corner to "fetch a policeman." He returned in an even worse temper, and was told by the lady that she were a man instead of a woman she would kick him down the steps. Fortunately, this bold woman retains the enlargement, frame and all. Though she did not pay a penny, she will probably hear no more about the matter. That is the way to treat these gentry; they have no legal means of enforcing their impudent claim. We understand that there are two picture-enlarging firms working in the district at the present time. This paragraph refers to only one of them.

THE STEREOSCOPE APPLIED TO ASTRONOMICAL RESEARCHES.*

I.

[From "Popular Astronomy," to which publication we are indebted for the translation.]

We have recently seen the stereoscope, an instrument old in principle, become, in skilful hands, an unexpected means of investigation. This modest apparatus, which seems rather to belong to the entertaining side of natural philosophy, suddenly appears as a new resource which promises to be fruitful in very varied applications. It is based on one of the simplest principles, whether we consider the old stereoscopes of Wheatstone (1838), and of those of Brewster, (1850), or the more perfect apparatus which dates only two years back and which is designated under the name stereo-comparator.[†]

Let us recall how we see objects in nature. Let us suppose an observer whose eyes are normal, to be looking at any object whatever, as O, Fig. 5, at a distance which shall not be too

Fig. 5.

great. Each eye being directed toward the point O, the two visual rays form an angle p , which is the parallax of the object. The observer must then turn the right eye C. a little to the left of its normal position, the left eye C₂, a little toward the right. It is the physiological effect accompanying the corresponding tension of the muscles of the eye which produces in us the idea of distance, or, what amounts to the same thing, the sensation of relief. If O draws nearer, we feel that we must make an increased effort to follow it with the two eyes; on the contrary, if it recedes, the eyes tend to take again a parallel position, and we perceive without the help of any other means that the distance is increasing. Yet the perception is limited for the naked eye; experience has proved that for a distance greater than 400 to 500 meters, i.e., about 450 metres, the eye becomes incapable of feeling the sensation of relief. For such a distance the angle p is reduced to 0.5, the normal separation of the eyes being 65 mm.

Then let us suppose that, instead of looking at a real object, two stereoscopic images i_1, i_2 are examined through two lenses, L₁, L₂, placed before the observer's eyes C₁, C₂ (Fig. 6); let us

Fig. 6.

suppose at O₁ is represented any object whatever on the first image i_1 . This same object is found again at O₂; for example, on i_2 . If the two points O₁, O₂ are perfectly placed, the eye C₁ will see the object O₁ following the direction C₁ O₁; while the left eye will see the same object in the direction C₂ O₂; the two impressions on the retina unite in one producing the

illusion of a single object O, which would be situated at the intersection of the two lines C₁ O₁ and C₂ O₂. If A is the distance of the eyes, A¹ that of the two corresponding points O₁ and O₂, the distance D at which the object O seems to be found in space, is obtained by

$$\frac{D-f}{D} = \frac{A^1}{A}, \text{ whence } D = \frac{Af}{A-A^1},$$

indicating by f the distance of the two images from the eyes of the observer. The lengths f and A are constant for the same apparatus and the same observer: let us note that if the images include several details for which the distance A¹ is the same, the different points will appear to be removed the same distance into space. If A¹ is greater, the corresponding point will appear in a plane more distant than the first. One can easily demonstrate this by arranging so as to vary the distance of A¹; for this purpose let us represent the two corresponding figures O₁, O₂ by two points, one of which, O₂, is fixed, and the other, O₁, movable by the aid of a micrometer screw. We seem to see but one point suspended freely in space; bringing O₁ nearer to O₂ it seems as though the point O travelled along the line O₂ L and was approaching us; on the contrary removing O₁ further from O₂, the point O appears to us more and more distant on the same line.

It is seen at once that this very simple arrangement may serve to obtain the distance of any object. Let us project the image of the points, which we have placed in the focal plane of the lenses, on the object examined; let us move the movable point O₁ until the virtual point O, which can be made to change by the aid of the micrometer screw, seems to be at the same distance as the object whose distance we are trying to find. This being done, the apparatus gives A¹, and, knowing the constants of A, the distance D is found from the relation given above. Such is the simple principle of the stereoscopic telemeter. A piece of apparatus constructed in this way would necessarily be of very limited usefulness. The distance between the eyes is, in fact, a very small base of operation for determining considerable distances. It was to meet this difficulty that Helmholtz invented his reflecting telemeter (1857), in which the course of the luminous rays is directed according to the following designs (Fig. 7).

Fig. 7.

The luminous rays come from a distant object O after having undergone two reflections by two groups of parallel mirrors, which adjust them to the distance the eyes are apart. To the eyes the object O removed to a great distance will seem to be at the point O, the intersection of the two straight lines C₁ m₁ C₂ m₂, along which the eye receives the luminous rays coming from O, and respectively parallel to the directions Om₁ and Om₂, going from the object to the mirrors m₁ and m₂. Everything takes place as if the observer's eyes were themselves spread apart to the distance of the mirrors m₁ m₂; in other words, the base of operation for perceiving the relief is multiplied by the ratio of the distance of the two mirrors to that of the eyes. Dr. C. Pulfrich of Jena has taken up this idea in his stereoscopic telemeter and made considerable improvement; instead of the simple mirrors of Helmholtz we find here two telescopes twice bent, whose eye-pieces can be

* From February No. 1904, Bulletin of the Astronomical Society of Belgium. Translated from the French by Miss I. Watson, Department of Modern Languages, Carleton College, Northfield, Minn.
[†] These notes are taken from a series of articles published by Dr. Pulfrich in the "Zeitschrift für Instrumentenkunde," 1901, Nos. 8, 9; 1902, Nos. 3, 5, 6, 8, Berlin: J. Springer.

adjusted exactly to the distance of the eyes, and whose objectives are separated to a distance of one and a half metres, in the largest kind constructed by the firm of Zeiss. So that, if for simple vision the stereoscopic effect reaches to an estimated distance of 450 meters, the new apparatus will extend to about 10 kilometers; in order to make it the most practical possible, movable points are not used, but a series of fixed references; they are placed at the focus of each of the objectives and, stereoptically combined two by two, they appear like a series of points, farther and farther removed and forming a scale of distance. The distance is read immediately by noting between what references any object seems to be. It is needless to insist upon the great advantage that one may gain from this apparatus, especially in topography.

It is remarkable to be able to estimate distances of several kilometres with the aid of a base having a length of not more than one and a half metres, yet it is desirable to be able to determine still greater distances; for instance, if it were desired to measure that of the shooting stars, or of taking measures of the aurora borealis, it is certain that the base ought to be 10 or 20 metres at least in order to make the same conditions as for a landscape. And if one wishes to apply the same means to determine the distances of celestial objects—moon, planets, comets, even stars—the dimensions of the earth itself would not be sufficient to furnish a proper base.

To avoid this difficulty Mr. Pulfrich has constructed an ingenious instrument which he calls the stereo-comparator.

Fig. 8.

(Fig. 8.) It serves the same purpose as the stereoscopic telescope, but instead of making the measures on the object itself which is to be studied, operations are made on photographic images which are examined with the aid of a binocular microscope at a great distance from the objective. If one should unite in an ordinary stereoscope the photographs taken with the help of two instruments whose optical axes are parallel and are at the distance of the eyes, one would evidently experience the sensation of projection such as there is in reality. If the two objectives are separated farther, for instance up to one and a half metres, the combination of the two photographs will give rise to an increased relief just as in the telemeter. But nothing hinders us from increasing indefinitely, so to speak, the distance between the two positions from which are taken the views to be combined in the stereo-comparator. The photographic instruments are arranged with this purpose, as Fig. 9 indicates; in 'C' the photographic chamber is supported by a mounting similar to that of a theodolite. It turns about a horizontal axis, AA, to which is attached on the one side a graduated circle L_1 , and on the other side a bent eye-piece OP; the axis AA can move in azimuth by rotation around a vertical

axis V, a rotation whose amplitude is read by the aid of horizontal circle L_2 . A standard with three levelling screws and furnished with a level makes possible the setting of the instrument. In front of the eye-piece may be placed a Prand prism P, turning about the axis of the eye-piece and reflecting the luminous rays at a constant angle of 90 deg. with the optical axis of the telescope. The observer placing his eye at the eye-piece O sights along the line PP' perpendicular to the optical axis of the photographic system, an axis itself determined by cross lines traced on a glass plate arranged in front of the sensitive plate. The two instruments are oriented, so that the focus of each eye-piece is seen the image of the prism covering the objective of the other eye-piece. When this condition is fulfilled, and the inclinations of the lines of sight to the horizon are the same—their inclinations being read by the

Fig. 9.

graduations R_0 of the circle L_1 —one is certain of obtaining two photographs on plates situated in the same plane, perpendicular to the base used. The operations to be done on the stereo-comparator are of remarkable simplicity. According to conditions, one will make use of a single instrument placed successively at the two posts of observation, or one will use two identical instruments operating simultaneously. The first case will present itself when there is a rise of ground, for instance, or again in stellar photographs; but here the parallelism of the optical axes during the two photographs will be obtained by using a fixed star as a guide. On the other hand, the two instruments will be used when one wishes to obtain stereoscopic views of clouds, lightning flashes, shooting stars, etc.

G. VAN BIESBROECK.

A GREAT compliment has just been paid to British art by the French Government, which has purchased for the nation the picture by Mr. H. Hughes-Stanton entitled "Poole Harbour from Studland, Dorset," exhibited in this year's Paris Salon.

THE Cyko Camera Distribution.—Messrs. J. J. Griffin and Sons, Ltd., inform us that a large number of photographers desirous of taking advantage of the opportunity they are offering for the advantageous purchase of Cyko cameras, have been deterred from so doing by their inability to examine the instrument at the warehouse in Fardinia Street, Lincoln's Inn Fields, London. For their convenience, therefore, the under-mentioned firms have been appointed agents, from whom the cameras may be obtained, and all particulars relating to the prize competition therewith. This cancels Condition 3 of Messrs. Griffin's offer:—London: City, Benetfink and Company, 107 and 108, Cheapside; West End, London Stereoscopic Company, 106-108, Regent Street; Aberdeen, J. Henderson, 164 Union Street; Bournemouth, F. W. Hornby, 132A, Christchurch Road; Bradford, T. C. Bridges, 6, Charles Street; Bristol, Hodder and Co., Ltd., Wine Street; Cambridge, Beall and Son, 25, Sidney Street; Manchester, J. T. Chapman, Albert Square; Reading, Tunbridge and Wright, 84, Broad Street; Salisbury, Atkins and Son, Market Place.

Example of Low Power Telephotography (reproduced by permission of Colonel R. W. Shipway).

of the BRITISH JOURNAL OF PHOTOGRAPHY.

THE ARTISTIC ASPECTS OF PHOTOGRAPHY.

[A paper read before the Royal Photographic Society.]

I.

THE vagueness of the title is not free from guile. At the same time, it admits, upon compulsion, of very precise definition. It is therefore a title that will serve our purpose in whatever emergency our subject may lead us. By a process of elimination we may get nearer to its meaning. Thus: Scientific aspects are not in our way to-night. To commercial aspects we may thankfully give the go-by. Social, political, and topical aspects may be bundled together and passed by on the other side. Allowing scant service even to pictorial aspects, in the narrow sense of the word, we shall have arrived in the end at some notion of what the artistic aspect of photography really signifies. It may surprise some that the artistic should be thus deliberately separated from the pictorial. The divergence, however, is none of my making. Certainly, their union, when it does occur, is the perfection of wedded conditions; but this only proves that the two things are not synonymous terms for the same thing, as is very generally supposed. The pic-

torial is a matter of the intellect; the artistic a matter of the emotions. The one born of the head, and the other of the heart, inasmuch as this, that the man who works can tell you exactly the whys and wherefores of his pictorial methods; but of his artistic movings he may be almost unconscious, or at least have no answer beyond "It pleases me thus, I know not why."

In other words then, artistry—to use a convenient substantive in default of one that should exist in our language, but does not—artistry is, in the main, very little different from good taste. Good taste is a desideratum of value all the world over, and saves us, in common life, even as a sense of humour saves us, from snares and pitfalls, degeneracy and suicide. In the world of pictures, however, where it is absolutely indispensable, good taste assumes a more important rôle than it plays in common life. Treasured and cultivated it becomes so powerful as to be, in reality, the artist's refuge on all conceivable points connected with picture-making—his final mentor and guide in all his ideas. A photographer should be as jealous of his taste as a surgeon is of the cleanliness and keenness of his scalpel.

To neglect it, to vilify it, to cause it to bow before convention, tradition, or fashion, is to stultify it utterly sooner or later. Without such good taste, such artistry, to drop the paraphrase, the happiest pictorial compositions will be but dry bones—handsome skeletons if you will; but dry bones still, lacking warmth, breath, and soul. It might be quite easily proved, however, that in the photographic world, handsome skeletons of the kind indicated readily find admirers and customers. Such a fact should have no weight with him who has any regard for the artistic aspect of his subject—such a fact, indeed, is in close connection with the commercial aspect. Buyer and seller work and react one upon another. The style of thing that is praised, noticed by the Press, bought, or even talked of in one season, is usually imitated and reproduced in the next. This, too, is purely commercial.

The fact that a photograph is much discussed is no proof that it was ever worthy of discussion. Fame and fortune are capricious folk, often paying their visits at the wrong houses. But fame and fortune are wooed by one and all. Even photographers are not proof against the temptation to do the thing that is popular in the face of admonitions from their own taste. Such temptation, however, does not attack the taste which has been cultivated, and is, therefore, strong enough to say "Get thee behind me." Once again then do we see the prime necessity of taste-cultivation. Should the question arise as to how it is to be taken in hand, it would be easy to lay down one or two general ideas, which the student might readily adapt to his own conditions. The process is a simple one, there is no mystery about it whatever. The student must be true to his own likes and dislikes, at the same time that he seeks in nature more and more of the former, and changes as many dislikes as he can into likes. In this connection it may be observed that numerous and strong animal-versions do not as a rule betoken a broadly artistic temperament. The young lady—school of art student perhaps—who is so much concerned about the precise tint of a piece of ribbon that is "to go with" a certain hat and a certain hue of hair and complexion, is more the slave of prejudice than the master of artistic subtleties. The fear of being caught tripping is the mainspring of nearly all artistic yearnings of this class.

It is for this reason that I advance the wisdom of trying to like instead of to abhor, and particularly to love nature in what are popularly supposed to be her repellent moods. A quarter of a century since it was universally held that the countryside is only worthy in the summer time. As a matter of fact, the country usually looks its worst at that time, especially if the summer is hot and dusty. The colour of the landscape in the frosty months; or when springs lays a tender sprinkling of the purest green over all and opens her most charming flowers; or in autumn when green, gold, and brown melt one into the other above and strew the ground beneath; the colour at these times, I say, is infinitely more eloquent, and the skies are infinitely more poetic, than during July and August, when nature has matured, when her functions are fulfilled, and her glorious decline has not set in. Photographers, fortunately, have not overlooked this great truth, and that in spite of the fact that the charm of the colour is at present not within their reach. Whilst in landscape, however, there is little, if anything that is actually ugly, it cannot be gainsaid that where subjects have the human element, or evidences of it, as in figures or architecture, there may occur combinations of items that fall below the perfection found in irresponsible and insensate Nature, and in such cases I would urge the student to the utmost to have regard to his first momentary promptings of displeasure or discontent rather than to wait for that sophistry or that worldly notion that may win him over in a few minutes. Generally speaking, it may be taken for granted that when a man dislikes any natural scene, the balance of

chances are that he is wrong: but that when he dislikes any particular figure or architectural subject, the balance of chance are that he is quite right. A further aim in the training of the taste is that the student should strive to secure those qualities in his work that attracted him in the subject—a task that in photography really resolves itself into one of technical and executive perfection. Above all, he must keep his ideas guileless and free from all taint of the cant of societies and coteries and clear of fashion's allurements. Should he verily see nothing admirable in certain transatlantic portraits of little white noses coming out of great black backgrounds, he should be readier to place his camera under a steam hammer than suffer himself to produce that style of thing for the sole reason that certain men here and certain papers there have, rightly or wrongly, extolled it. It would appear that such a natural and evolutionary course as I have referred to for the formation of good taste, is too irksomely slow for some. Quite recently there has been set afoot a demand for a more systematised and rapid initiation into pictorial secrets. As though, forsooth, there existed any tricks of a trade in truly artistic work, only awaiting demonstration to be understood and put into force. Those who look to societies, to magazines, to lectures, and so forth, for a short and easy way of making pictures, have yet to learn that whatever little crumbs of knowledge may be picked up thus, are scarcely worth stooping for. The large and valuable part of artistic knowledge is subject to no written laws, and hence it follows that theories upon it can never be more than profitless pedantry.

If, for example, the Royal Photographic Society were to lay itself out for an elaborate system of pictorial education for the improvement of its members, what, may we suppose, would actually result? Will those members who are admittedly clever and artistic honestly say that their work would be enhanced by the theorising of this or that man no more artistic or clever than themselves? It would be tacitly agreed that such lectures and demonstrations were for the beginners in the art. But the beginners, I hold, would be better left to their own slower and surer crawlings. In science and philosophy the crammed or rapidly-taught tyro may perhaps make a show of a sort; but in art the newly-taught tyro is an anomaly, for there he can make no rapid notes of concrete facts. There are no dates or quantities to learn off by heart, and he can watch no experiments performed before him. In a word, as all preaching or discussion about art must ever remain mere expression of opinion, and as opinions will be found to differ in every exponent at whose feet the helpless student sits, he will find in the end that he has no course but the slow sifting and assimilating process, which is the work of years. Lectures or debates upon art are splendid tonics and refreshments for the initiated, who can match against such their own experience, or test anew their old convictions. To the uninitiated they are but as the discussion of mysteries in an unknown tongue. A more excellent way, meet for those who are earnestly striving, is that of self-instruction. It is a more effective and more pleasurable way of attaining artistic enlightenment, and it is the only way. Unfortunately it is a way not open to all, for at the very outset the student must be endowed with a congenial temperament. In that fact lies the very fate of a photographer. Millions buy cameras and try hard; but a few only "have it in them," as we say, to make beautiful pictures. With the natural and personal advantages of a congenial temperament, and a receptive and responsive mind, the student may start on his course of training by learning how to use his eyes—one of the most difficult of the things he has to compass—for there is looking and looking; even as a cunning jeweller, on the one hand, and the proverbial fowl on the other, may look at the same pearls and diamonds.

By the mere act of facing the riddle of art in nature, he will

ly assimilate a deal of the knowledge he covets. For he is a curious one in this respect, that the answer comes lying upon the question. Even by such a slow process, the knowledge comes less tardily to the simple starrer, the reader or debater, to whom indeed it seems never. By reason of the honour done to me by my being in this position to-night, I am emboldened to express my best opinion that the special and further fostering of pictorial work of this Society would hardly be accompanied by marked improvement in its exhibited pictures. I am that the cry is a heartfelt and praiseworthy one: "Show me how to select my subjects and how to make attractive pictures." But I am sadly aware also that the only truthful answer to that cry is short and severe to hopelessness—"Teach me." Who else in fact can teach those intangible and subtle qualities that make a picture either good or bad, irrevocable of the handsome skeleton in composition it may possess? Does the aspirant set his hopes upon a trick to be taught; or a mode to be adopted? If so, what manner of trick or mode will I advise him to prefer out of the goodly number that he has himself upon his gaze? Upon such a road of tuition he will find nothing but bewilderment, confusion, and vexation, barring the way to the height he seeks. Let him turn to the path. Let him give up the notion of sending a picture "next year, like So-and-So's fine thing, and let him see himself by his eyes, silently. To look at Nature and to take pictures and then at Nature again is the way. In matters of style and method, it is a mistake to try to persuade oneself against one's own judgment. Respect your own taste and never coerce it. The way to be successful is to be original, oneer if one can; and that can never come of imitating another else. The truest and finest originality is always found in the ordinary and beaten track of natural fact. He who sets laws, conventions, and traditions at defiance; who does something simply because no one has been foolish enough to do it before, and who abuses his materials for the purpose of making folk look twice, is by no means a pioneer. He is only an ill-advised creature playing at topsy-turvy. The student to succeed should be one which actuates the student to produce as nearly as possible, without violation of natural fact or principle, the charms felt in the ordinary view of visible objects, and towards the attainment of this desire there can be no aide, no mentor, but the student's own taste, unsullied by the thought of a short cut to notoriety.

"Keep your ain gait," is the most profitable motto. No lecturer can mix before your eyes the elixir of artistic life; no philosopher has the philosopher's stone up his sleeve. Many have attempted to impart artistry by oral means, but it remains unteachable. What may be taught, however, and what may like this I have now the honour of addressing may, and teach, is, facility of execution, scientific knowledge, and all that comes within the definition of technique. To attempt to promise the moon. The immense value of technical training lies in this fact, that it produces men clever at their work, and without this, the most gifted artist is as hapless as a poet who cannot write his own language. Language must be before ideas. They are the subtler part. They comprise feeling, the unnameable appreciations, the irresistible prompting of the artistic temperament. They come to the student who finds himself growing more clever in the manipulation of his materials. He may have had dreams; but they were imbecile of realisation before. Now he finds that he can begin to substantiate them, and, in turn, his improving execution suggests fresh ideas. He goes to Nature and reads her by the light of his craft, not in the wildly generalised way of his earlier method. Possibilities of pictures present themselves before he went blindfold; for knowing better what can be done with his materials, he recognises subjects that have tired other workers; subjects that, before, he sought in

vain outside their framed presentments. He is now, in fact, a picture maker, but who, except himself, has instructed him?

In the case of the individual who listens to theories, and studies diagrams, things are vastly different. He tries to digest somebody's notions of "balance," of "radiating lines," of "masses" and "curves," and turning to some grand work with a reputation, either finds them all falsified, or fails to find them at all. Especially may this happen in photography, where it rarely occurs that nature answers exactly to conventional requirements. The finest photographs that have ever appeared will not be found to owe much to deliberate selection on conventional pictorial lines. They have been the outcome of individual taste and untrammelled predilections. It will now become apparent why the pictorial was separated from the artistic aspect of the subject. The former may be learnt, but is worth little, at least, in photography; the latter is unteachable; though it may be learnt by intuitive means. So much for the earnest student seeking to form a fine taste. What is the position of the man who to-day can claim success, fame, and sometimes opulence—the finished photographer? Speaking as one to whose lot it has fallen during the last five years to examine critically all the best pictorial photographs of this country, and a great quantity of those from abroad, I must confess that, on the whole, I have been as much shocked as I have been charmed. What has shocked, however, has by no means been found in the modest work, bearing the unknown name. On the contrary, as much of such work as is good enough to find a place in an important gallery is usually characterised by an honesty of purpose frequently wanting in the work of those with reputations. In the eyes of the general photographic world, perhaps, these great ones alone are worthy of the laurels continually offered to them. For my own part I find, making one or two notable exceptions, that the man in the middle position, being neither a raw beginner nor a world-wide celebrity, frequently offers the most artistic work. He has knowledge and experience, and is as yet not so blasé that he must go beyond the bounds of licence and galvanise his sensations into a thrill by some out-of-the-way unlawfulness. Such practices are no doubt of use in keeping the name of the deprecator famous for something; but they are distinctly decadent.

Reverting to a matter already touched upon, we shall find that most lapses from good taste are committed in the name of originality. Far be it from me to deny any man the artistic right to do, and even to display, the maddest thing under the sun, if he truly thinks that what he is doing has a purpose or a charm. Individuality comes about in that very way, notwithstanding the fact that in some cases, individuality is attained by the cheapest possible means, and should cause shame and humiliation where it often results in pride and aggressiveness. But if it is admitted that no great sort of individuality consists in wearing strange clothes, because all other men elect to dress alike, what can be said of the man who would ape a Beau Brummell, and look round for applause? Short of such slavish imitation for imitation's sake, however, it must be granted, of course, that it is salutary to take note of one's neighbour. A hermit life will bring no good. Interchange of opinion, comparison of criticism, all such mutual methods, honestly carried out, make for progress, because in the work and opinion of others, we can find something worth the having, which we ourselves lack, and something unpleasant of which we may resolve to rid ourselves. But all beyond this tends to a baneful diffusion of ideas. The self-centred life is the sterling one, where the ideas are perhaps fewer, but have greater depth of earth wherein to flourish. What is to be deplored is not the original idea, but the desire to be original—a distinction with a difference. And the desire to be original appears, in my humble opinion, to be at the root of all the regrettable tendencies of photographic picture-making to-day.

F. C. TILNEY.

Exhibitions.

CAMPBILL PHOTOGRAPHIC EXHIBITION (GLASGOW).

The photographic exhibition and competition, promoted by the Museums and Galleries Committee of the Glasgow Corporation, was opened last week in the Camphill Gallery. The exhibition, which is an excellent one in every respect, is to last six months, and is the first of its kind to be held in the Camphill Gallery, although many similar exhibitions have been held under the auspices of the Corporation in the People's Palace on Glasgow Green. It is principally confined to pictorial work, but is divided into three sections—namely, a competition section, an historical and processes section, and an exhibition section. In the first-named £20 was offered in prizes, which was awarded at the discretion of the judges, Messrs. Tom McEwan, R.S.W.; William Young, R.S.W.; and J. Craig Annan. There were about 200 entries for competition. The historical and processes section, though small, is a very interesting one, the principal exhibitors in it being Mr. William Lang, Mr. William Young, and the Corporation of Glasgow. In the processes class the exhibits chiefly consist of some very fine examples of three-colour printing from Messrs. Andre and Sleight of Bushey, Hertfordshire. In the historical class there are two cases of interesting books, documents, and photographs connected with the history of photography. The exhibition section contains about 300 entries, including some very fine pictures of mountain scenery from the Scottish Mountaineering Club, Mr. Inglis Clark, the secretary of that club, and Mr. Alfred Holmes, of Bradford. Messrs. Lizars exhibit enlargements from half-plate negatives taken by the Lord Provost, Sir John Ure Primrose, Bart. Mr. J. Comrie Smith, of Giffnock, shows some fine portraiture studies and reproductions of oil paintings; and Mr. D. W. Kyle, Glasgow, has sent several beautiful flower studies. The Corporation of Glasgow show a fine photographic reproduction of the famous Ghent altar piece painted by the brothers Van Eyck. Among the principal professional exhibitors are Messrs. T. and R. Annan, W. M. Warnecke, George Romney, Robert Turnbull, Glasgow; and Messrs. A. G. Milne, Brechin; and W. Crooke, Edinburgh. The most prominent among the amateur exhibitors are Messrs. V. C. Baird, Broughty Ferry; James Craig Annan, Glasgow; Reginald Craigie, London; R. C. Dalgity, Brechin; Charles H. Emanuel, London; Professor Finlay, Aberdeen; T. M. Foulis, Edinburgh; A. Geekie, Coupar Angus; F. J. Mortimer, London; Dr. Charles F. Grindrod, Malvern; W. F. S. Holt, Manchester; Alexander Keighley, Steeton; Arthur Marshall, Nottingham; and J. C. S. Mummery, London. The arrangements for the exhibition were made by Mr. Rainy, assistant curator, assisted by Mr. William Young and Mr. Tom McEwan. Preceptor R. M. Mitchell, chairman of the Museums and Galleries Committee of the Glasgow Corporation, performed the opening ceremony. The following is the list of awards in the competitive section:—F. J. Mortimer, London, "The Winter of Life," £3; T. N. Foulis, Edinburgh, "A Saxony Shepherd," £3; Daniel M. Filshill, Glasgow, "Evening," £2; Arthur Marshall, Nottingham, "The Prie-Dieu," £2; W. Inglis Clark, Edinburgh, "Ben Nevis from Allt a' Mhuilinn," £2; R. Berry, Blackrod, Lancashire, "The Student," £2; Christian H. Curle, Melbourne, "Ringing a Wheel," £1; Fawcett Clapperton, Edinburgh, "A Lowland River," £1; Charles Kirk, Glasgow, "Willow Wren Feeding Young, from Life," £1; W. Milroy, Kingston, "The Balloon," £1; Professor Finlay, Aberdeen, "A Squall on the Bay, Hamilton, Ontario," £1; S. G. Kimber, Southampton, "The Monks' Entrance," £1.

FORTHCOMING EXHIBITIONS.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.
July 14 to September 30.—Vienna Photographic Society. Secretary, W. Burger, Karmelitergasse 7, Vienna 11.
August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Cradidge, Jubilee House, Andover.
August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.
September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.
September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.
October 1-30.—Berlin International Photographic Exposition, Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.
October 19-22.—Rotherham Photographic Society. Hon. sec., Hemmingway, Tooker Road, Rotherham.
November, 1904. Ilford and District Photographic Society. sec., W. N. Beal, 155, Thorold Road, Ilford.
November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.
November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.
November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
November 21-26.—Sheffield Photographic Society. Joint Secretary, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.
November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.
December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.
December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102 West 101st Street, New York.
December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
December 13-20.—Southampton Camera Club. Hon. Secretary, S. Kimber, Oakdene, Highfield, Southampton.
December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.
January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.
February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.
June, 1905.—Northern Photographic Exhibition. Secretary, F. Issott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News" 9, Cecil Court, Charing Cross Road, London, W.C.
June 30.—Kodak. £1,000 in cash prizes for pictures taken Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.
October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.
October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugman, Brussels.
October 31.—Coxin. 68 prizes for users of Coxin. Judging two pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
November 1.—The "Graphic." £50 in cash prizes. Manag. Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.
December 31.—Barnet. Nineteen classes. Prizes valued at £2 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.
March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

MESSRS. L. GAUMONT and Co., of 25 and 22, Cecil Court, Charing Cross Road, London, W.C., have informed us that their "Professional Chrono," which was the only bioscope machine to obtain the highest award at the Paris Exposition of 1900, has recently been selected by the United States Commissioner of the St. Louis Exhibition of 1904, as the only cinematograph machine to be used in connection with this exhibition.

The Beneficent Influence of Hobbies.—The boy who learns to collect and classify fossils or flowers or insects, who has acquired a lot of photography or chemical experiment, and similar knowledge, has laid the foundation of much happiness in life. A hobby keeps up some interest for leisure hours, and lifts one out of the groove of one's everyday work. Suppose a lad has learned to use tools—the struggle for existence is becoming greater every day, and on one or ever be the worse for having learned some handicraft. On the contrary, if a young man has to go abroad to a new land to make his living he may find the hobby of his youth of great utility. Almost any hobby teaches business habits, and instils into the mind that sort of ambition which no one need be ashamed of—ambition to excel.

THE LATE W. BATES.

It is a much regret to have to record the death of Mr. W. Bates, photographer, of Chertsey, Surrey, which took place on the 14th inst., in his seventy-eighth year of his age. The deceased gentleman, in whose company we spent many pleasant hours on the occasion of an annual river trip not many months ago, traced his photographic career back considerably more than half a century, and was, perhaps, one of the oldest photographers in the country, as he certainly was the most urbane, catholic in taste, and cultivated. Skilful with the brush, his leisure was devoted to painting or sketching, and in the charming little Chertsey studio over which he so presided with such skill and success, the backgrounds, frames, and other of the artistic impedimenta of a portraitist's necessary *tridra* were the products of Mr. Bates' facility for design.

To many readers of these lines Mr. Bates will be chiefly remembered as the sponsor and manufacturer of "Bates's Black," but his singular modesty concealed a personality of rare charm and attraction. In earlier years his energies found an outlet in the direction of invention; in later times his portrait work and his painting monopolised his attention. The delightful studio in the old-world little Surrey town of Chertsey has sent out a great deal of excellent portrait work which if it has not often secured the very doubtful privilege of illustrated newspaper publicity has yet deservedly won the esteem and appreciation of a large and refined clientèle. By the death of Mr. Bates photography is distinctly the poorer, for as a man and an artist he was of a very high type indeed.

The business at Chertsey will be carried on by a son of the deceased gentleman, Mr. S. T. Bates, who inherits many of his father's gifts and to whom we wish every success.

THE LATE W. BATES.

Eastman Kodak Company of New Jersey.—The usual quarterly dividends of $1\frac{1}{2}$ per cent. (being at the rate of 6 per cent. per annum) on the outstanding Preferred stock of this Company, and of $2\frac{1}{2}$ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common stock, have been declared by the Eastman Kodak Company of New Jersey, payable on July 1, 1904, to stockholders of record at the close of business on May 31, 1904.

MEMBERS and friends of the London and Provincial Photographic Association are reminded that the summer outing will be to St. Paul's Cray Common, Chislehurst, to-morrow (Saturday). The Bickley Hotel, at which supper will be served, is at the entrance to the famous caves recently discovered, and which are well worth exploring. Reserved accommodation will be provided on the train leaving Cannon Street at 2.20. Tickets at special fare can be obtained at the station from the hon. recorder. Return from Chislehurst at 10.6 p.m.

THE PRESS ON THE "B. J." JUBILEE NUMBER.

OUR readers will be interested to learn that the leading newspapers of London and the Provinces have referred in terms of the highest praise and approval to the special Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY, which was published on the 10th inst. We select the following typical examples from the very large number of notices that we have received:—

"A capital Jubilee number."—"Birmingham Daily Gazette."

"Cannot fail to attract the attention of a large circle of readers."—"Aberdeen Daily Journal."

"The text portion of this souvenir number will interest every photographer."—"The 'Publishers' Circular.'"

"Amateur camerists will find the number abundantly interesting as well as instructive."—"Northampton Herald."

"This Jubilee Number deserves its producers' claim for it that it is 'a unique event in photographic journalism.'"—"The 'Referee.'"

"The Story of the BRITISH JOURNAL OF PHOTOGRAPHY' will be read with great interest by all engaged in photography."—"Derbyshire Advertiser."

"The Jubilee number of the BRITISH JOURNAL OF PHOTOGRAPHY is a most excellent one, on which we heartily congratulate our contemporary."—"The 'English Mechanic.'"

"The Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY is a very handsome production, and its contents are of a most interesting character, being contributed by many leading authorities on our art-science."—"Dundee Evening Telegraph."

"The proprietors of the BRITISH JOURNAL OF PHOTOGRAPHY have just issued their Jubilee number—a huge production, full of valuable information, and profuse with half-tone illustrations."—"Halifax Courier."

"The Jubilee number of the BRITISH JOURNAL OF PHOTOGRAPHY appeared on June 10. This capital issue was something of which its proprietors might well be proud. This number was, indeed, a unique event in photographic journalism."—"Book and News Trade Gazette."

"The BRITISH JOURNAL OF PHOTOGRAPHY, established in 1854, has issued an exceedingly interesting Jubilee number, full of special papers and pictures relating to all branches of the photographic art. A feature of the number is a series of portraits of leading photographic experts and inventors."—"Lloyd's Newspaper."

"The BRITISH JOURNAL OF PHOTOGRAPHY has issued a leviathan number to commemorate its completion of half a century of usefulness. The contents are, of course, to a large extent reminiscent, and they include articles by several of the leading spirits in the photographic world."—"Liverpool Courier."

"The BRITISH JOURNAL OF PHOTOGRAPHY for June 10, 1904, is an exceedingly interesting issue which should be in the hands of all photographers. This particular number celebrates a unique event in photographic journalism—the Jubilee of the BRITISH JOURNAL OF PHOTOGRAPHY. The editor and publishers are to be congratulated on its production."—"Pharmaceutical Journal."

"The BRITISH JOURNAL OF PHOTOGRAPHY Jubilee Number was issued on the 10th inst., and is excellent. The number includes an illustrated history of the BRITISH JOURNAL OF PHOTOGRAPHY since its foundation in the year 1854, the interest attaching to the article being increased by the appearance of portraits of the various gentlemen who have filled the editorial chair, the last on the list being, of course, Mr. Thomas Bedding, F.R.P.S."—"Church Bells."

"The proprietors of the official organ of the photographic art in England have marked a unique occasion by the publication of a remarkable issue of over seventy pages, exclusive of advertisements, at the ordinary price. Needless to say, the work is of exceptional value to the photographer, both amateur and professional, and at the same time interesting to the general public. The editor and his staff may be congratulated on the success of their enterprise."—"Oxford Times."

"The BRITISH JOURNAL OF PHOTOGRAPHY has just issued its Jubilee number. The editor is Mr. Thomas Bedding, F.R.P.S., and the issue contains no fewer than thirty special articles on the most popular and prominent phases of modern photography, each written by an authority whose portrait is given. The number also includes an illustrated history of the journal since its foundation in 1854. All photographers, amateur as well as professional, will find this special number very interesting."—"Westminster Gazette."

"The BRITISH JOURNAL OF PHOTOGRAPHY has reached its jubilee, and a special number has been published, containing articles by experts on various phases of the art. Photomicrography, journal photography, picture postcards, a half-century of camera evolution, and colour photography are a few in a list of papers too long to detail in full, and the number as a whole covers an immense field. Rare and contrasts between then and now naturally occupy a good share of attention in this jubilee number."—"The 'Western Daily Press.'"

"The amateur of to-day is apt to forget for the most part the art which he pursues has already a history extending back considerably more than half-a-century. The photographer is reminded by the Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY that its journalism has now a record of 50 years. The number is a special one in many respects, and includes an illustrated history of the journal since its foundation in 1854, and has contributions from many of the leading writers on matters photographic."—"Glasgow Evening Times."

"A copy of the jubilee number of the BRITISH JOURNAL OF PHOTOGRAPHY has been sent to us. It is quite a bulky publication, and votaries of the camera should find it very interesting. The editor, in a prefatory note, candidly admits that the aim kept in view in its compilation was to produce a publication which, when placed in the hands of an intelligent photographer who has not hitherto been a reader of photographic journals, shall so far attract his attention to some branch of his subject that he will become a permanent and interested reader. In other words, it has been prepared and published with an eye to business."—"The 'Dublin Daily Independent.'"

"The year 1854 saw the inauguration of the Crystal Palace and the BRITISH JOURNAL OF PHOTOGRAPHY. It is to-day curious to find that the periodical in question was originally founded and edited by photographic and journalistic amateurs at Liverpool, where it was published for some years before it moved to London and took its present title. This week's number, being a Jubilee one, is made up of mixed reminiscences and congratulations, which are votive offerings from editors of other photographic publications, and from various photographers. The accompanying portraits of the contributors are as interesting as their writings."—"The 'St. James's Gazette.'"

"We have received a copy of the special illustrated number of the BRITISH JOURNAL OF PHOTOGRAPHY, which celebrates the existence of that paper for fifty years. It contains, besides articles on 'Progress of Lens-Making,' 'Photo-Micrography,' 'Three-Century Work,' etc., a history of the journal's life, giving details of its growth from the 'Journal of the Liverpool Photographic Society' in 1854 to the present time; during which period such editors as Sir William Crookes, J. Traill Taylor, and others, whose portraits are published, have raised it to perhaps the leading position in photographic journalism."—"Engineering."

"Last week's BRITISH JOURNAL OF PHOTOGRAPHY was a special number designed to commemorate the completion of its half-century of existence. Founded and edited in Liverpool by a committee of amateur journalists who belonged to the local photographic society, after a chequered life it shifted to London, where for some years it had to struggle for priority with the 'Photographic News,' which journal was, in its palmiest days, looked on as the leading organ. It has so successfully managed to keep out all that have attempted to poach on its particular preserves. That the 'B.J.P.' may look back on its jubilee as the starting time for yet further prosperity will be the universal hope."—"The 'Morning Post.'"

"We have received the Jubilee number of the BRITISH JOURNAL OF PHOTOGRAPHY, which was established in 1854. As might be expected, it is profusely illustrated, and the pictures, which are practically all photographs, are most artistic and splendidly reproduced. Several of the most prominent exponents and practitioners of the photographic art contribute to a number which very well maintains the reputation of one of our most excellent magazines. 'Picture Postcards,' an article by the Rev. T. Perkins, is specially interesting just now, and 'Photographic Lenses of the Past Half-Century,' by Mr. Philip Everitt, is a valuable contribution to the history of photography. The number is readable and informative, and most interesting throughout."—"The 'Times.'"

"The year 1854 is a long way back in the history of photography and the art-science was very different then to what it is to-day. It was in 1854 that the first number of the BRITISH JOURNAL OF PHOTOGRAPHY appeared, and now, in 1904, the journal is celebrating its

...celebrating it in a grand number containing thirty
...by men who lead, or who have led, the progress of photo-
...y. There are portraits of them, too; men whose names we
...as the first men in the photographic world. That Mr. Bed-
...who has for so many years occupied the position of editor,
...have been seriously ill just before the jubilee number appeared,
...feel sure, lamented by all who knew him. But I believe that
...recovering now, and heartily congratulate him, both on the
...and the excellent number in which it is celebrated."—"Pall
... Gazette."

...the proprietors of the BRITISH JOURNAL OF PHOTOGRAPHY com-
...rate this month the jubilee of the paper by the issue of a
... jubilee number. To photographers generally, especially those
...verpool, it will prove of great interest, as it was in the year
...ing the inauguration of the Liverpool Amateur Photographic
...iation that that society put forth this journal, then called the
...pool Photographic Journal, resting their claims to public
...rt upon the widely extending interest in the several branches
...otographic art. There are many still living who, we feel sure,
...appreciate in this history the brief sketch of that delightful
...nality. Mr. H. Greenwood. This number of a paper undoubtedly
...e forefront of photographic journalism, is worthy of careful
...al by all lovers of the photographic art."—"Liverpool Journal
...mmerce."

...the past half century photography has made enormous strides.
...atus and processes have been revolutionised, the amateur votary
...e groping numbers fifty years ago were few and far scattered, is
...embarrassingly ubiquitous, and publications on the art are as
...iful as the most ardent devotee could desire. Considerable
...est attaches at this time, therefore, to the attainment of its
...ee of the BRITISH JOURNAL OF PHOTOGRAPHY. To mark this
...ne event in photographic journalism a special number has been
...d containing thirty thoroughly comprehensive articles on the
...popular and prominent phases of modern photography, brightly
...en and attractively illustrated by competent authorities and
...rimentalists. A notable feature is an illustrated history of the
...nal since its formation in the year 1854, the writer being the
...or, Mr. Thomas Bedding. The production should prove valuable
...professionals and amateurs alike—"Glasgow Evening News."

Photography has now dozens of publications specially devoted to
The oldest photographic journal is, however, still the best. The
BRITISH JOURNAL OF PHOTOGRAPHY publishes this week its Jubilee
number. Fifty years ago taking a photograph was an operation of
ense difficulty. Now every schoolboy can do it. Many thousands,
including schoolboys, can do it very well. The BRITISH JOURNAL
OF PHOTOGRAPHY has always moved with the times. It has numbered
ngst its editors Sir William Crookes (who edited it so far back as
, and it is to-day the most authoritative exponent of photography,
for the professional and the amateur. The Jubilee number con-
s articles on every variety of photographic subject by the best-
own writers. Probably the most interesting is that containing the
iniscences of Mr. G. Watnough Webster, of Chester, well known
over the world in connection with his pictures of Mr. Gladstone."—
"Freeman's Journal."

In celebration of the jubilee of the BRITISH JOURNAL OF PHOTO-
GRAPHY last week's issue, greatly enlarged for the occasion, contains
cially contributed articles by some of the foremost photographic
rkers and writers in the country on the history and progress of
various branches of photography during the past 50 years, as
well as valuable contribution on photographic processes, etc. Many
of the writers have been identified with the JOURNAL for 20, 30, and
on 40 years, whilst a special feature of the number is a history
the paper from 1854 to 1904 by the editor, Mr. Thomas Bedding,
illustrated by reproductions of copies of some of the earliest issues
the JOURNAL, and photographs of the various editors and assistant
editors who have been connected with the paper since it was
established. One of the most readable articles in the number is by
E. W. Foxlee on 'Photography Fifty Years Ago.'—"Lancashire
Daily Post."

THE "B.J." JUBILEE NUMBER—SOME MORE READERS' OPINIONS.

OUR readers continue to send us letters of congratulations on the
"B.J." Jubilee number, of which the following selected extracts are
representative of the favourable criticisms evolved:—

"Congratulations upon your Jubilee number—it is splendid.—T. S.
PRICE."

"Congratulations upon your marvellous Jubilee number; it is,
indeed, a record.—H. SNOWDEN WARD."

"A most interesting number, and I trust the forerunner of many
more.—WILLIAM GAMBLE."

"I think you may feel quite satisfied with the Jubilee number.—
W. R. BLAND."

"I must congratulate you on your Jubilee number; it is quite the
best I have seen of the "B.J."—FRANCIS PHILLIPS."

"Like everyone else I was most favourably impressed with the
Jubilee number. May you be at the helm and eclipse even this when
the Journal reaches its Diamond Jubilee.—HECTOR MACLEAN, F.G.S."

"Allow me to tender my hearty congratulations for your Jubilee
publication. As a reader of seven years duration, it has been a
weekly companion of much value and increasing interest. I have been
pleased with the progressive spirit, and sincerely wish it a very long
and universally useful future.—GEO. TAYLOR."

The British Journal PHOTOGRAPHIC ALMANAC FOR 1861

SOUTH London Photographic Society.—At the last meeting of this
society, Mr. C. E. Kenneth-Mees, B.Sc., F.C.S., gave a paper, illus-
trated with lantern diagrams, on "Slow Plates for Rapid Work."
As the result of many experiments he had come to the conclusion
that rapid plates were only of use in the studio, and contrary to the
generally received opinion, possessed no advantage over slow or
medium plates even for fast focal plane work. By means of strong
development, long continued, he had obtained results with the same
exposure on photo-mechanical plates equal to those on rapid plates
normally developed, but as the developer used was 1 in 4 Rodinal,
the plan is not likely to commend itself to the average amateur. Only
plates that will develop without bromide are of any use on this plan,
and development must be carried to its limit, which, with 1 in 4
Rodinal is about ten minutes. As a result of Mr. Kenneth-Mees'
experiments, several firms of plate makers are investigating the pos-
sibility of raising the height or the development curve of ordinary
plates—a point which the lecturer considered of far more importance
than increasing speed.

FLOATING A PHOTOGRAPHIC COMPANY.

Last week Mr. Justice Grantham and a special jury heard an action brought by Sir William Henry Broadbent, the physician, of Brook Street, against the Earl of Dunmore, Great Cumberland Place; Count Max Hollander, Westbourne Terrace; M. Paul Boyer, Boulevard des Capucines, Paris; and Paul Boyer, Ltd. (in liquidation), of Moorgate Street, for a declaration that an allotment of five hundred Preference shares in Paul Boyer, Ltd., was null and void, for the return of £250, for an indemnity, and for other damages. Further, there was an allegation of fraudulent misrepresentation, and damages were claimed for alleged misfeasance, breach of trust, and contract, etc. The defence was a general denial of the allegations. Mr. Lawson Walton, K.C., and Mr. R. J. Willis were counsel for the plaintiff; Mr. Rufus Isaacs, K.C., Mr. F. Gore Brown, K.C., and Mr. E. Ford for Count Max Hollander; Mr. Eldon Bankes, K.C., and Mr. Martelli for Lord Dunmore; and Mr. Atherley-Jones, K.C., and Mr. Edward Ford for the company and M. Paul Boyer.

In opening the case Mr. Walton said Sir William Broadbent sought to recover damages from the defendants in consequence of his having been induced through their instrumentality to take shares in a company of which they were directors. In Paris there was an enterprising photographer known as Paul Boyer, who was said to have invented some marvellous processes in photography. He considered it would be a good thing if his business could take the form of a company, and be put on the English market. With the assistance of the other defendants this project took practical form, and ultimately a company was registered with the object of buying all that M. Paul Boyer had to sell. The capital was to be £60,000 in £1 shares. Of these 24,000 were to be Preference and the remaining 36,000 Ordinary shares. Lord Dunmore had had considerable experience in connection with company directorship and was chosen chairman while one of the members of the board of directors was Count Max Hollander. On one occasion Count Max Hollander visited Sir William Broadbent as a patient, and in a sympathetic moment, said Mr. Lawson Walton, at the termination of one of his visits, he produced the prospectus of the company and said it was one of the best things going. As a result, Sir William Broadbent signed an agreement by which he was to underwrite five hundred shares, and he gave a cheque for £62 10s. as a deposit on application. But a more complete frost never attended a public appeal in any enterprise of the kind. The people of the United Kingdom and France had prospectuses sent to them broadcast, but there was only one response, and that came from Scotland, the land of the keen and astute. One solitary Scotsman applied, but he did so with that caution which characterised his race, for he only desired three shares. Count Max Hollander also saw another eminent medical man, namely, Sir Thomas Barlow, on the subject of underwriting the company, and with a certain amount of success. Continuing, Mr. Walton said that besides paying the £62 10s. in the first instance, Sir William had to pay a further call of £187 10s., making a total of £250, to the liquidator, inasmuch as the company went into liquidation without doing any particular amount of business. The company was hopelessly waterlogged from the outset, and the defendants had acted most wrongly, to say the least. Counsel then read the various resolutions passed by the board, one being that the directors voted to themselves certain fees. These amounted to a total of £146 to Lord Dunmore and £106 13s. 4d. to two others. This was all done out of the underwriters' money, and beyond that very arduous and responsible work he (Mr. Walton) could not trace that they had ever done anything else in connection with the company. Mr. Walton then dealt with the accounts which had been kept by M. Boyer in connection with his French business before the flotation of the company, saying that the accountants' certificate stated that it was true that the profits of Boyer were £8,000 per annum, whereas it was found that they were less than £2,000.

His lordship remarked that he could not understand how it was that counsel and solicitors had anything to do with the promotion of companies without seeing that the best and fullest information was obtained from the books, etc. The certificate in this case was absolutely false as to its verification of the profits of the defendant Boyer.

Mr. Rufus Isaacs said that no doubt an elaborate system of

falsification of Boyer's books had been carried out. In spite of that had been done, Boyer could not be got hold of. Notwithstanding what our Foreign Office had attempted in the matter and the issue of a warrant by Sir John Bridge at Bow Street, nothing could be done with regard to bringing Boyer to book.

His Lordship remarked that he could not understand why English people could go and placidly put their money into or save French ventures like this before they knew absolutely everything about them. Why, the South Sea bubble was not in it without matter of this kind.

Mr. Lawson Walton, referring to the prospectus of the company, said the stock-in-trade included in the purchase represented a value of £25,000.

Mr. Justice Grantham: Of course, the solicitors had verified the statement in the prospectus.

Mr. Gore Browne said the list was checked and ticked off item by item.

Mr. Lawson Walton said it was perfectly obvious that the value was grossly over-estimating the value.

Mr. Justice Grantham: There can be no doubt, according to the statement made, that he wanted money and that the whole thing was a fraud.

Mr. Bankes said he believed the business was flourishing, but his complaint was that the profits were misrepresented.

Mr. Lawson Walton said they also complained of misrepresentation as to the value of the assets. Proceeding, he said that in the statement produced to the Registrar of Joint Stock Companies the liquidator said the estimated amount of the assets was £511s. 6d., which of course included the uncalled capital. He believed that only 10s. per share was paid.

Mr. Gore Browne said the company had rescinded the contract to purchase, so that the assets did not any longer belong to the company. When the company rescinded the contract they got judgment in the Court of Chancery, but had not succeeded in enforcing it, because they declined to pay a sum of 80,000 fr. registering the company in France.

Mr. Justice Grantham: And this is what English people advised to go into!

Mr. Lawson Walton said there was not a tittle of evidence to show that the property was worth even a small fraction of the value alleged.

Mr. Chantrey, an accountant and liquidator of Paul Boyer, Ltd., said he knew nothing of the signatories. As liquidator he had attended at Paris to take possession of the property of the company, but failed. Boyer had fine premises there which were elaborately fitted up as a photographic business. He could not express his opinion as to the value of the stock, but he considered that the negatives were very valuable, because Boyer was photographer to the French President and had negatives of many notable persons from which he made large sums of money. The British Ambassador was now approaching the French Government to see whether the unfortunate company could not get justice from Paul Boyer. They could get the judgment registered in France without payment of the 80,000 fr. duty he had no doubt that Boyer would pay up.

Mr. Justice Grantham said it would seem as if the French Government, by putting on an extraordinary duty, had made themselves party to a fraud.—Witness said that if he could enforce the judgment he could take possession. Boyer was a fairly substantial man, and in France they dreaded bankruptcy more than in this country.

Mr. Justice Grantham: That is why the Government, being paternal or a maternal Government, protects them by not allowing any one to register a judgment against them.—In cross-examination by Mr. Bankes witness said he investigated Boyer's position as far as he could, and ascertained that he was a member of the Legion d'Honneur.

Mr. Justice Grantham: Does that mean very much in France?—Witness: I am afraid not, because I have taken means to put the matter before the French Ambassador in this country, and no step has been taken to remove him.

In cross-examination by Mr. Rufus Isaacs witness said that if the business was making £8,000 a year the price asked for it was not excessive or outrageous. The minutes of the company disclosed that the directors had taken every step possible to bring M. Boyer to book. The warrant for the arrest of M. Boyer was issued by Sir John Bridge, on the sworn information of Count Max Hollander.

respect to money received by the company. Boyer had not been in his country since. Proceeding, the witness said the French found that Boyer had been guilty of fraud, but he could get further in the matter. Hollander had paid up all the calls on shares. In the whole of his inquiries he did not find any evidence of negligence in the performance of their duty as directors to justify a charge of negligence being launched against them. This was the plaintiff's case.

Mr. Eldon Bankes submitted that there was no case against Lord Dunmore.—Mr. Lawson Walton, in reply, contended that there was no case against Lord Dunmore, and that it would be premature to dismiss him from the action. Lord Dunmore was a party to the formation of the prospectus.

His Lordship said it was such an extraordinary case that he did not hold that there was no evidence against Lord Dunmore. Mr. Rufus Isaacs submitted that there was no case against Lord Dunmore, but his Lordship said he could not stop the case against him.

Mr. Eldon Bankes then opened the case to the jury for Lord Dunmore. He said he should satisfy the jury that his client took more trouble than most directors did to satisfy himself that this was a company with which he could properly associate himself, made very strict inquiries in Paris as to the company. Part of the time his client was away from the country, and he could not be held responsible for acts done in his absence without his permission. He asked them to judge his client's conduct in the case having regard to the facts, and thought they would then see that he had taken every precaution and was reasonably careful.

Mr. Rufus Isaacs then opened the case for Count Hollander and said that much that his friend had said applied to his client as well. His client could only be made responsible if it could be proved that statements to the plaintiff were a lie, and there was no evidence to bear this out. His client also went to Paris and saw the flourishing business that was being done, and satisfied himself that was a good business.

Mr. Justice Grantham said the extraordinary part of the case was that the mischief was done at a meeting at which the only directors present were M. Paul Boyer and M. Lamprecht. These two passed a resolution, but it was extraordinary that the other directors did not look into it afterwards.—Mr. Isaacs said it was apparent that what was done was for the purpose of going to allotment. They told the meeting knowing that the other directors were abroad. The plaintiff was entitled to a declaration that the allotment was null and void, but not to bring his action against the defendants for breach of duty and negligence. Count Max Hollander, as well as Sir William Broadbent, had been swindled by the falsification of the books which was not discovered by the accountant.—Mr. Justice Grantham said that what had altered the complexion of the case was a good deal was the fact that Lord Dunmore, Count Max Hollander, and the solicitors and their families had put money into the company.—Mr. Isaacs said that that was so, and they appeared to have been swindled all round by M. Paul Boyer. It had been suggested in the course of the case that Sir William Broadbent had gone into many transactions with Count Max Hollander, and had lost in all of them. Sir William had made considerable profit in some of the transactions.

Count Max Hollander, picture dealer, Bond Street, said he had carried on that business for thirty years. He first became acquainted with M. Boyer a few months before the introduction of this company through M. Lamprecht. Sir W. Broadbent had had business with him for many years in connection with both pictures and underwriting companies. In several of the latter affairs he had come off successfully. An exhibition of M. Boyer's productions took place at the witness's gallery. It was connected with instantaneous photography. In August, 1898, he (the Count) saw Sir William Broadbent. After consulting him as a patient he opened the business with which this action was concerned. Sir William went to the gallery, and then the negotiations began.

Had you any doubt about its being a sound investment?—No; I put my money in it, and so did my partner. He (the defendant) had nothing, however, to do with the actual promotion of the company. Since the liquidation he had done all he possibly could to obtain redress for those who were so unfortunate as to place their money in the company. He had, moreover, tried every way that

he could to bring Boyer to justice.—Cross-examined: His remuneration was not excessive as a director. On the contrary, he never charged his expenses to Paris when he went there to make investigations. He never heard before this action that the promoter had allotted shares to him in consideration of his services.

Lord Dunmore said that he first heard of Boyer's business in his stockbroker's office. After due inquiries were made in England and accountant's certificates were perused, together with the opinion of counsel, he went to Paris and saw M. Boyer's establishment. As to the promotion of the company, the witness denied that he ever took any part in it, nor did he ask any one to subscribe or underwrite the shares. In the summer of 1898 he had a very severe attack of gout and went to America. He had confidence in his co-directors, and thought he could safely leave the affairs of the company in their hands. He was particularly impressed with M. Boyer, who was "one of the most charming men he had ever met." Being a "Chevalier of the Legion of Honour," Boyer was, he thought, above suspicion.

Continuing, the witness said that when he came back and asked what had happened, and was told that 16,000 shares had been subscribed, he had no knowledge that only one application came from the outside public. He did not know till four years after that Ordinary shares had been allotted to him. It was a piece of great impertinence.—Cross-examined, he denied that he ever considered that his name was put up in the company as that of a mere figurehead.

His Lordship thought there was no case to go to the jury because there was no evidence of fraud, but on an appeal from Mr. Walton he did not insist on this view.—Mr. Walton then addressed the jury on behalf of the plaintiff.—His Lordship, in summing up, held with regard to the limited company that the allotment was not null and void.

The jury returned a verdict for the defendants, but added a rider to the effect that they were strongly of opinion that the defendants committed a serious error of judgment in failing to call a meeting of underwriters in order to lay before them the fact that the condition precedent to the underwriting letter had not been fulfilled.—His Lordship entered judgment with costs for the defendants, Lord Dunmore and Count Max Hollander. Stay of execution was granted on the usual terms.—Mr. R. G. Willis, for the plaintiff, asked for judgment against Paul Boyer.

Mr. Justice Grantham: Oh, yes, that shall be so.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June	Name of Society.	Subject.
27	Southampton Camera Club.....	Priest Competition.
28	Royal Photographic Society ..	Instruments for Stereoscopic Investigations. Mr. C. E. K. Mees and Mr. S. E. Sheppard.

2		Outing. Leigh, near Southend.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 16.—Mr. Child Bayley gave an instructive and extremely interesting lecture on the Alhambra, Spain, illustrated by lantern slides of great technical excellence, the negatives having been made with a hand camera and developed by the time method. Mr. Harvey Piper who was present was charmed with the pictures and with the lecturer's lucid description and legends, and pointed out the many beauties of Moorish architecture and its difference from our heavier Gothic style.

Mr. Drage was sure that the hand camera had more possibilities than were generally taken advantage of, and quoted Mr. Cembrano as saying that just the same work could be undertaken with a hand camera as with a stand camera.

Mr. Child Bayley, in response to queries, said that permits to photograph in the Alhambra could be had on application, and that 4s. or 5s. per day would cover hotel expenses.

News and Notes.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Mr. Roderick J. McLean, 1, Sussex Place, Widcombe, Bath, for his negative "Castlecombe, Somerset."

IN the Photographic Section of the forthcoming exhibition organised by the Royal Cornwall Polytechnic Society (August 16-20), Mr. H. W. Bennett, F.R.P.S., will take a leading part in the judging and management.

COLLENETTE, Limited.—The above-named Company has been registered with a capital of £1,000 in £1 shares. Object: to carry on the business of photographers, artists, portrait painters, miniature painters, framers, photographic teachers, importers, and manufacturers of and dealers in chemicals and other preparations and articles, compounds, oils, paints, colours, pigments, and varnishes, dye-ware, paint, and colour grinders, makers of and dealers in photographic, electrical, and scientific apparatus and materials, etc. No initial public issue. Table A mainly applies. Registered office: 30, King Street, Manchester.

MR. WILLIAM ANDREWS, photographer, died at Wexford on Saturday evening, 11th inst., after a very brief illness, of peritonitis. He had been connected with the county for about forty years, and was well known in his professional capacity all over County Wexford. Mr. Andrews was a nephew of the late eminent German artist, Professor Gluckmann, who practised in Dublin half a century ago, and it was under that great artist that the late Mr. Andrews studied and served his apprenticeship. The deceased, too, was most popular all over County Wexford, where his genial disposition made him many friends. The funeral to Crosstown cemetery on Monday was large and representative.

POISONING by Cyanide of Potassium.—At the time when cyanide of potassium was the almost universal fixing agent for (collodion) negatives there were few suicides by this poison until that of the late Whitaker Wright. Since then there have been several. On Friday last an inquest was held at Malvern College concerning the death of Gerald Harris, 17, the son of Colonel Harris, of Saltburn, who died on Thursday from the effects of cyanide of potassium. It was stated that the deceased had been a student at the College for four years. A year ago he was warned for irregularities. Some improvement followed for a time, but on Tuesday he was again spoken to and told that he would probably have to leave the school. He was greatly upset, and next morning took poison. A verdict of "Suicide whilst of Unsound Mind" was returned.

AUTOMATIC Picture Gallery (1904), Limited.—This Company has been registered with a capital of £3,000 in 2,900 Preference shares of £1 each and 2,000 ordinary shares of 1s. each. Object: to acquire the business of the Automatic Picture Gallery, Limited, to adopt an agreement between E. H. Frith, of the one part, and the said E. H. Frith, J. H. Birch, and F. G. Kerly of the other part, and to carry on in the United Kingdom, the United States of America, and elsewhere, the business of exhibitors of stereoscopic views, owners and manufacturers of machines for automatic delivery or other action, exhibitors, showmen, advertisers, dealers in photographs, pictures, prints, and engravings, etc. No initial public issue. The signatories are to appoint the first directors. Qualification, £50. Remuneration, £50 each per annum. Registered office, 20, Denman Street, London Bridge, S.E.

ENDOWMENT of Scientific Research.—Mrs. Percy Sladen, of Northbrook Park, Devonshire, in the desire to perpetuate the memory of her late husband, Mr. Walter Percy Sladen, sometime secretary and vice-president of the Linnean Society, has undertaken to devote the sum of £20,000 to the promotion of scientific research, particularly in the subjects in which he was chiefly interested. She proposes to assign this sum under the name of the Percy Sladen Memorial Fund to certain trustees, in the first place of her own appointment, who are directed to employ the income arising therefrom, in their uncontrolled discretion, to "any research or investigation in natural science, and more especially in the sciences of zoology, geology, and anthropology." They are also empowered, if they think fit, to accumulate the income for the purpose of fitting out, or assisting to fit out, any expedition designed to further such research.

GUM Bichromate at the Royal Photographic Society.—The Secretary of the Royal Photographic Society informs us that M. R. Demachy, of Paris, has consented to give a second exhibition of prints by the gum bichromate process. The increasing attention that is being given in this country to the gum bichromate process suggests that the exhibition will be still more popular than which M. Demachy gave here a few years ago. The exhibition will be opened at 66, Russell Square, on Wednesday, June 22, and public will be admitted as usual on presentation of address, between the hours of 11 a.m. and 7 p.m. It is hoped that the prints may be retained until about the middle of July. Everybody interested in the gum process and in pictorial photography is invited to view the exhibition, which will include some sixty examples almost entirely new to this country.

THE annual conversazione of the Society of Arts will take place at the Royal Botanic Gardens, Regent's Park, on Monday evening, June 27, from 9 to 12 p.m. The central portion of the Gardens will be used. The Gardens will be illuminated with coloured lamps and also by the Kitson incandescent oil light. The conservatory in the club house will be open. The reception by Sir William Abner, K.C.B., D.C.L., F.R.S., chairman, and other members of the Council will be held at the entrance of the conservatory, near the Broad Walk from 9 to 10 o'clock. A selection of music will be performed by a string band of the Royal Artillery in the conservatory, and by a band of H.M. Irish Guards in the Gardens, commencing at 9 o'clock. A vocal and instrumental entertainment, under the direction of Mr. H. Tipper, will be given at intervals in the club house. Tickets will only be supplied to non-members on presentation of a letter of introduction from a member. Light refreshments (tea, coffee, ice, claret cup, etc.) will be supplied.

TUESDAY, June 21, was the longest day—a day upon which British people are supposed to be entitled to a longer spell of sunshine than at any other time of the year. The longest day celebrated its 100th anniversary without splendour. According to the almanacs the sun was shining for rather more than sixteen hours and a half. The fleeting moment in which he was revealed to the naked eye of the Londoner hardly altogether made up more than a couple of hours. Save at its birth and its death, the longest day, like many other lengthy things, was excessively dull, and although we have had a hotter and better spell of weather since, it was hardly the sort of day the photographer who relies on the mechanical exposure table would regard favourably. Gleams of sunshine at early dawn and dewy eve were rather tantalising than satisfactory to a town which had been all day vexed by itself under a grey pall of cloud. With the assistance of an efficient north-west breeze these clouds contrived to keep the thermometer in a chastened condition all day long, and there is no every evidence that the clerk of weather has repented of his unbecomingly natural conduct during the summer (!) of 1903, and we shall probably not hear of quite so many postponed society excursions on account of the unpropitious weather.

Patent News.

The following applications for patents were made between May 1 and June 4, 1904:—

Focussing Cloth.—No. 12,611. "Focussing cloth." James Henderson.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

THE B. J. JUBILEE NUMBER.

To the Editors.

Gentlemen,—One of the features which particularly struck me in connection with your marvellous "Jubilee Number" was the difference of opinion as expressed by two of your contributors. For instance, in an enterprising article by Mr. W. R. Bland, the suggestion is urged to utilise the medium of gum bichromate; on the other hand, Dr. Emerson writes that the process is dead.

Perhaps Dr. Emerson will supplement his statement with information to the basis on which he arrives at his conclusion.—Yours, etc.,
J. PAGE CROFT.

Madant Chambers, New Street, Birmingham.
June 18, 1904.

To the Editors.

Gentlemen,—Your very interesting "Jubilee Number" has arrived, and if it has had the same success everywhere as with me I am sure its desires will be filled to overflowing, and I hope the success of the BRITISH JOURNAL OF PHOTOGRAPHY will go on increasing, as well as its subscribers, and if we are almost sure not to see its hundredth anniversary of existence, I hope you will see its seventy-fifth year at least. I have been much interested in Mr. J. A. Sinclair's letter in the "Jubilee Number," but I must confess that he has not convinced me about the universal superiority of the hand camera over the tripod camera, and I maintain my sayings about usefulness of both, according to the results which are wanted, and if the first view taken in Milan was better obtained without tripod, the other one taken in London might just as well have been obtained with a tripod, as I think that the stoning business of a tripod user is almost played out everywhere now, even in backward Spain, and I think the elegant tripod over a black box to look at the finder is now as well known, and attracts as much attention as the old-fogey tripod user. Furious as it may seem, I have noticed that the use of tripods with cameras is on the increase, at least, here in France, and fully one-third of the hand cameras seen carried are accompanied by a small telescopic tripod. There must surely be some reason for it. As to rapid plates being equal and superior to slow plates, I would like to know why several firms insist upon inflicting on us many as eight different speeds when one only (the most rapid) is the best if not too slow, yet I should think that different speeds necessitate much larger expense than only one speed. This is another foolish or archaic delusion to be added to the fallacy of a tripod camera as against a hand camera.—Yours very truly,

ALBERT LEVY.

Asnières (Seine),
June 13, 1904.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—Until recently I was under the impression that spirit photography had ceased to be looked upon seriously, but now it seems to be a recrudescence of the subject.

Under any circumstances, what possible explanation can be found for so-called spirits seeking out a photographic plate and reducing their size in order to accommodate themselves to it without the intervention of any lens? as stated in some of the correspondence on the subject.—Yours, etc.,
E. D.

June 17, 1904.

To the Editors.

Gentlemen,—I have followed with interest the correspondence in the "B.J." on the above subject. There are some points good enough for the ordinary morning paper, but not for a photographic journal. I read last week, and have read before that spirit negatives can be taken without a lens or camera. If the thing is a negative it is produced by light or some kindred energy, and if there were no lens the energy in question would fog the whole plate. Will some photo-

graphic spiritualist explain the new system of securing photographs without either camera or lens? I read, I think, in F. Marriot's book that the spirit requires a longer exposure, and therefore after capping the lens after the exposure for the human sitter, it must be left some time for the spirit to impress the plate with its image, the cap being no impediment. If the cap were an impediment, surely the front and bellows were no impediment, and why was not the plate fogged? I could quite understand there being some radio-active image drawn on the inside of the dark slide, which it took time to get impressed on the plate. Why, Mr. Editor, do you not take the thing up, and investigate it in the interest of your readers? I should like to see three persons photographing with stereo cameras at the same time and from different directions, all taking away their plates, and developing at home.—Yours truly,
L. M.

June 20, 1904.

To the Editors.

Gentlemen,—Permit me to say that the extract from my paper on the above was not made by me, though my name appeared at the end. The reporter has summarised it very fairly, but, probably through pressure of time and space, from the first half only. In the discussion which followed, in showing two of the five photographs taken at various times of my niece, I explained that one was in fulfilment of a promise she had made to me through a medium in Glasgow, and that the child was seen and described by a clairvoyant at the time she was being taken in London. About twelve months later she was taken with me again, dressed as before, but holding her head and hands in a different position, and this time she was also seen and described by a lady who was present, and a moment afterwards by the photographer when he entered the studio. I pointed out that in the later one the pattern of the carpet had been reflected in the astral or luminous light, which gave somewhat the appearance of double printing. This your reporter has humorously rendered into "where astral carpets are in general use."

In America spirit photography is much more in evidence than with us, and in "Unseen Faces Photographed," by Dr. H. A. Reid, of Los Angeles, Cal., a number of cases are given, accompanied by the photographs, where the spirit visitors have been recognised as friends and relatives. One gentleman, a professional photographer of thirty years' standing, after a most careful and critical examination, had, in March, 1900, two portraits taken. He took his own plates and developed them himself in another studio, the medium, Mr. Wyllie, never touching them in any way. Mr. Disler, the sitter, in his sworn affidavit, says, "Imagine my surprise and great joy when, upon developing, I saw the correct picture of my spirit mother, two grandfathers, grandfather, and a spirit control."

In my paper I had explained that a photographic medium was one who supplied a magnetic or luminous aura which was made use of by the unseen workers, and, of course, with constant use this would permeate his camera, making it much easier to obtain manifestations than with that of a stranger. Some forty years since a spirit control gave the following explanation, quoted in "The Veil Lifted":—"Spirits impress their image on the plate by depositing thereon repeated layers of magnetism. According to their respective powers of affording this, so is the impression more or less distinct. The magnetism must be of the same texture or affinity as that possessed by the operator; it is accomplished by a rapid vibration of the spirits' magnetic emanation in depositing layer after layer, and the process is this: The operator, by frequent manipulation, saturates his material with his aura, etc., etc." Each psychic photographer seems to have a slightly different method, and produces a distinct class of work, but they one and all appear to have their respective spirit guides, who assist the invisible sitters to render themselves visible on the plate. One operator in America finds that he gets more satisfactory results by leaving the plates for a fortnight before proceeding with the developing, which tends to bear out the explanation given from the spirit side.

The following statement has been made by one of your correspondents respecting Mr. J. Traill Taylor: "We were in each other's confidences, more especially regarding my method of manufacturing shams. Conversations we had during his later years (the italics are mine) tended to convince me that he wavered in his opinions regarding certain results."

You, Sirs, by the timely and welcome reprint of his lecture given

in 1893, have conclusively proved what his views were two years previous to his death, and there is before me a most interesting address which he gave on this very subject in May, 1895, summing up his further experiences as follows:—"Here, however, is the point: these pictures were true and genuine throughout so far, at any rate, as concerned all those who were present; my tests were too good to admit a doubt of this. I, therefore, can afford to look with the greatest charitableness upon editors and photographers who, not having had opportunities of acquiring a sufficiency of knowledge, relegate these photographs to the limbo of fraud. I myself did so at one time, and can, therefore, scarcely blame them for doing likewise. Where blame rests is in their not scientifically investigating a subject which ought to be replete with interest to a photographer." There is no wavering about this, and within six months Traill Taylor passed on and took his first view of the spirit spheres.—Yours faithfully,
June 21, 1904.

H. BLACKWELL.

HISTORICAL.

To the Editors.

Gentlemen,—I notice with much pleasure the commencement of some articles on orthochromatic photography by Mr. E. J. Wall, anything coming from him on the subject of colour sensitive work will be read by the interested with much attention.

In the first instalment of his series, I observe that he credits the late W. K. Burton with being the first to suggest that the emulsion film should be dyed with ammonium picrate to obviate the employment of a separate light-filter. To the best of my recollection, this suggestion was made by Major-General Waterhouse in or about 1883, in connection with collodio-bromide emulsion (orthochromatic), and I am under the impression that at the time General Waterhouse attributed the idea originally to Albert of Munich. Burton certainly was not the first to advocate the use of ammonium picrate in connection with orthochromatic work.

I am writing away from home, so cannot refer to my historical notes on this subject. If I am wrong in my history, perhaps Mr. Wall will be good enough to correct me.—I am, Sir, yours faithfully.

June 20, 1904.

G. T. HARRIS.

Answers to Correspondents.

*** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

*** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

*** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

*** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- F. Platt, 25, Mint Street, Kendal. Photograph of Thos. Gūpin.
J. P. Lessels, 15, Crown Street, Aberdeen. Photograph entitled:—"The Smile that Won't Come Off." Photograph entitled:—"The Smile that Won't Come On."
J. T. Barnard, 12, Wansbeck Street, Morpeth, Northumberland. Two Photographs of Last Cattle Market in Morpeth Market Place. Photograph of Oldgate Bridge, Morpeth. Photograph of Sanderson's Bridge, Morpeth.
F. Gleadow, Heathfield, Stonegate, Leicester. Photograph of Mountain called "Le Corps qui Regarde," in Mauritius. Photograph of Head of the "Corps qui Regarde," Mauritius.
C. H. Thwaites, 12, High Petergate, York. Photograph of Mr. T. Tertius Noble.
Flowers & Nixon, 200, Bank Street, Alexandria, N.B. Photograph of the Kenton Public School Football Team.
L. Hart, 25, Triangle, Clifton, Bristol. Photograph of the Bishop of Clifton and Clergy.
H. R. Roberts, Temple Bridge Studio, Llandrinodod Wells. Photograph of Llanyre Bridge, near Llandrinodod Wells.

Photograph of View of Gutton Hall, near Redhill. Two Photographs of View from Redhill Common. Photograph of View of Gutton Town Hall, near Redhill.

BOOK WANTED.—"PRIM" asks: "Can you inform me of a publication

where I can find all about prisms?" In reply: All works optics deal with prisms. Dr. Von Rohr's is a good work, is about the latest published.

BARNARD.—Some of the portraits you send show much promise in lighting, posing, and retouching. Your carbon work appears good, and taking into consideration the unfinished state of others, we do not think you should have any difficulty obtaining a fairly good salary as operator.

"G. W."—We do not think we can recommend you to start a studio the strength of the prints you submit, unless you have private income. The photographs, however, show promise, you have not yet mastered the difficulties of retouching. Most of the portraits sent have lost all trace of modelling, and appear quite textureless.

"P. J."—We have nothing to add to what you were told in previous reply. If you print from negatives from which, through imperfect washing, the hyposulphite of soda crystallises out, you must expect to get stained prints. You should have thought every professional photographer knows that. We do not reply to correspondents by post.

UNEVEN TONES.—W. Wood asks: "Could you kindly assist me in tracing and avoiding the marks on photos herewith?" They show themselves in the paper before printing, and when mounted and burnished they show very prominently." In reply: The marks show on the paper before printing there is no value in avoiding them. Try another make of paper.

COPYRIGHT.—"E. F. R." writes: "Some time ago you expressed opinion in the JOURNAL that if I registered certain pictures photographs I could restrain the sale of a guide containing pirated pictures, although the guide was published before registration. I should be obliged if you could give me authority on the subject." In reply: If you refer to page 725 of the volume for last year you will find an article on the subject, and authorities quoted. We do not reply to correspondents by post.

OPINION WANTED.—J. H. BAKER asks: "Will you, please, tell me if it is a fault to show the sun's disc in a photograph like the one sent for registration? Do you think a good picture could be done in carbon from the negative, say in a green or blue tone? Would the green or blue look well, and, if so, which?" In reply: The picture perhaps looks a little more effective with the sun shown. A very good carbon enlargement could be made from the negative. Sea green, we should say, would be the better of the two colours mentioned.

REGISTRATION OF DESIGN.—"C. G. T." says: "I have designed a mount to hold cabinet photos. The outside measurement is 3 1/2 x 2 1/2. The mount has been very much admired, and consequently, should like your recommendation as to where to register the same to an advantage. Also, whether you could name any wholesale houses or manufacturers that would buy the patent?" In reply: The design must be registered at the Patent Office Design Branch, Southampton Buildings, W.C. You had better submit the design to some of the wholesale houses, such as Maron's, or Houghton's.

BOOK WANTED.—"C. H. T." asks: "Would you be good enough to tell me the author and publisher of the most reliable book of all kinds of photographic lenses? I require more of an Encyclopædia that explains treatment of lenses under various circumstances and climates. A book with a clearly defined index, readily specifying the purposes of various lenses. To sum the matter up, I need a book in methodical order containing advice on all kinds of lenses and their merits from all experts." In reply: The latest and most complete work on optics is that of Dr. Von Rohr. We know of no Encyclopædia devoted to optics—indeed there is no such work.

COLOURING.—"IGNORANT" says: "(1) I should be much obliged if you would tell me the proper medium to use for painting brown enlargements in oil colours. Will ordinary oil colours do? What must I mix them with, and must the photo (which mounted on canvas) be prepared with anything before commencing work? (2) Should the portrait be varnished, and if so, what? (3) How long should an ordinary 18 x 14 enlargement take to paint and dry?" In reply: (1) Ordinary oil colours, used by artists, mixed in the usual way. (2) If the enlargement is on glossy paper no preparation is necessary. It might, you like, be sized. The picture may be varnished or not. This is a matter of taste. (3) This, of course, depends upon the time expended in the finishing. The paint will dry in a day or two.

THE BRITISH JOURNAL JUBILEE NUMBER.

Special Jubilee Number of THE BRITISH JOURNAL OF PHOTOGRAPHY, which we published on Friday, June 10, met, we are pleased to say, with a most cordial and favorable reception at the hands of the photographic community—indeed, the success achieved was so striking and unanimous as to cause even ourselves, who had anticipated the Special Number would secure a wide degree of appreciation, the liveliest feelings of gratification and pleasure at the chorus of commendatory approval meted out to the issue.

Several extra thousands of the Special Jubilee Number have been printed, and they are selling rapidly at the ordinary price of twopence per copy, or by post twopence-penny. The number consists of a total of 132 pages, forms the largest ordinary issue of any photographic journal ever published in the United Kingdom. The contents include thirty special articles by the foremost photographic authorities of the time; a history of THE BRITISH JOURNAL OF PHOTOGRAPHY since its foundation; and about thirty original portraits of celebrities connected with photography; thus forming a unique and most interesting souvenir of the Jubilee of the oldest photographic journal in the world.

This souvenir number of the JOURNAL is in such demand, and is shortly likely to be scarce, readers at home and abroad who have not yet secured a copy are urged to do so without delay.

EX CATHEDRA.

The Jubilee of "The British Journal of Photography."

The "Wiener Frere Photographen Zeitung," in its issue of June 15, gives expression to the following appreciative remarks concerning our Jubilee Number, and we thank the Editor for his good-will:—"In the year 1850 the paper was known as the "Photographic Journal," and from the 1st January, 1860, it has borne the name of the BRITISH JOURNAL OF PHOTOGRAPHY. We have already had occasion to indicate the value the BRITISH JOURNAL has been to photography, and we wish to point out that we were its first congratulators in our January issue of this year, when no one else thought of the fiftieth birthday of this, the oldest and best professional photographic paper in the world. The Jubilee Number, which lies before us, bears witness again to the importance of the BRITISH JOURNAL, for it brings together in a volume weighing almost 400 grammes a collection of technical and historical papers relating to the development of photography and the BRITISH JOURNAL during the last fifty years. This is completed by a succession of biographies and photographs of the editors and contributors who have hitherto been associated with the paper. Among them is that renowned man of learning, W. Crookes. We will shortly give a more thorough review of this Jubilee, but meanwhile we convey to the Editor a repetition of the good wishes which we already expressed at the beginning of the year."

* * *

Photography as a Demonstrator.

At the present time it is a little difficult to imagine how science could be illustrated, or at least as it is, without the aid of photography. A photograph conveys a better and more truthful impression than does the most skilful drawing. At the final conversazione of the season of the Royal Society, last week, photography as an illustrator was, as usual, largely to the fore in several branches of science. One very interesting lantern demonstration with the modification of the cinematograph of plant movements was given by a lady, Mrs. Dukinfield Scott. The pictures were taken at intervals, which varied according to the rapidity of the motion of the plants, and extended over several days, and sometimes weeks, and the pictures, as shown on the screen, gave an excellent idea of the movements and the flowering of different plants. There were on view photographs from the high Andes of Bolivia and Peru, coloured lantern slides demonstrating the optical properties of mineral sections, colour-photographs of moths and butterflies in various stages of development. Sir Wm. Abney, whose method substitutes spectrum colour for the three colour glasses, showed examples. There were photographs

of weather phenomena, buildings struck by lightning, of solar and meteorological changes, cloud photography, etc. The lantern was in strong evidence during the evening on the ground floor, illustrating a great variety of subjects. When attending a conversation of any scientific society, and seeing how largely photography is always in evidence, one naturally wonders how science would now get on without it as an illustrator.

* * *

Betrayal at Jena.

"Photographische Kunst" on May 31 drew attention to the fact that the firm of Carl Zeiss had summarily dismissed four employés for betrayal of trade secrets. They had offered important drawings to a competitive optical firm in Brunswick, which, however, immediately informed the firm of Carl Zeiss of the fact. It appears that all four were married men with families, and enjoyed good salaries, with prospective rights to pensions, etc. Further particulars of this occurrence are published in the current number of our contemporary, according to which three of these workmen brought an action against the managers of the firm for unjustifiable dismissal without notice. The managers made a counter-claim for £150 damages. The following account of the proceedings is given in the "Leipziger Volkszeitung":—"It was proved that the workmen had been in receipt of less wages, whilst on the staff, than when formerly doing piecework. One of the men, who had latterly been in receipt of a weekly wage of 46s., had actually earned £25 less. The Court held that the firm must pay the three workmen 92s., 84s., and 72s. for loss of wages during the time for which they should have had notice, but it also granted the counter-claim for £150 against the workmen for damages, because the firm would have to instruct others to take the workmen's places. The Court did not find that trade secrets had been purloined; at most there had only been damage or injury." Evidently the law in Germany is more favourable to the employer than in this country. If the decision here had been that the men were wrongfully dismissed, we think the masters' case would have broken down completely. Unfortunately full particulars of the case are not given, and it is thus impossible to form a definite opinion of the case.

* * *

The Advantage of Small Cameras.

In the first May issue of the "Photographische Mitteilungen," the optician, Karl Martin, of Rathenow, published an article concerning the focus of a lens, and explained the effect on perspective the angle included might have. In the current number J. Switkowski, of Lemberg, whilst agreeing in the main with the writer of the article, wishes to point out that there are circumstances in which gain may attend the use of a lens of short focus. Especially is this the case, he says, when your means limit you to one lens only, in which case it is preferable to restrict the focus of the lens to the length of the plate. If the angle of the picture is found to be too wide, the defect may be remedied by cutting down the print. But it might be pointed out that a smaller and cheaper camera would serve the purpose, in which case a wide-angle rectilinear could be added to the outfit, without perceptible addition to the outlay. It is also the more rational course, as it would be necessary to trim the greater part of the prints taken with the camera of larger size. The other point which attracts our attention is the recommendation that the shorter focus lens has greater depth. The writer points out that it makes very little difference if a photograph be enlarged four or six diameters, if the negative be sharp, and it is implied that the shorter focus gives an advantage in definition. It is quite true, as stated by

J. Switkowski, that the depth of definition of two lenses varies inversely as the squares of their foci, but will prove that two photographs, made with similar lenses of different focus, and taken from the same standpoint, will show any difference in definition, when the same amount of subject in both is enlarged to a given size? Apart from something might be said about the grain of the plate, which case the longer focus lens would have the advantage. We quite agree with Herr Martin's recommendation to use a lens of shorter focal length than the diagonal of the plate, unless circumstances make it imperative.

Spy Mania in France.

About a month ago, it will be remembered, we cautioned English photographic tourists on the Continent to be careful where they used their cameras, lest they subjected themselves to the indignity of arrest and detention by too vigilant official anxious for promotion. In the *Standard* we read, last week, that another English tourist has been arrested as a spy at Brest. It is stated that he was arrested by M. Werdes, the Special Commissioner at Brest, whose subordinates, it is said, had been watching him for several days. As in Colonel Gordon's case the one referred to in the previous caution, the British Embassy received no information about the matter. The telegram to the "Standard" last week, it is mentioned that Captain Gye, the British Consul at Brest, will doubtless take up the case. It is this second arrest, occurring so soon after the other, which induces us to once more recur to this spy scare, and again caution our readers who may be projecting a tour with their cameras in France to be on the alert as to where, and how, they use their cameras; for, as a rule, a holiday trip is none too long and it is very undesirable that any portion of it should be curtailed by the tourist being arrested and confined, even a day while inquiries are being made. We again reiterate what we have said before, that English tourists with cameras, will do well to be provided with passports, although none may be necessary for the country visits. It proves the tourist's identity, and, to a great extent, proves that he is on innocent intent. In the event of an English tourist being arrested as a spy, the best way will be at once to communicate with the British Consul of the place, and if he be provided with an English passport, he will no doubt be quickly liberated, as the Consul will be assured of the holder's bona fides, whereas, without long inquiries may have to be made before he regains his freedom. A passport, as we said before, may be obtained at the Foreign Office without trouble, and at quite a nominal fee—sixpence, if we remember rightly; but it is so long ago since we obtained one that we almost forgot the exact cost. A passport, when obtained, does for a time. It does not require renewal whenever a foreign tour is made.

Photographic Manufactures in Germany.

The report of the Vereinigte Fabriken Photographischer Papiere, Dresden, and that of the Frankfurt Chamber of Commerce, relating to dry-plates, both give an unfavourable account of business during the past year. The principal manufacture of the Dresden firm is albuminised paper, but although the best has been done to push the sale of other articles to replace the falling-off in receipts for albuminised paper, the net profits this year have fallen to £21,400, against £28,200 last year. This shows a difference of nearly 25 per cent. The Frankfurt Chamber of Commerce states in its report:—"The year 1903 did not bring with it the anticipated improvement in the photographic trade. The industry suffers mainly from

causes. Professional photographers, who are the large consumers, have been subject to very keen competition in all large towns at the hands of stores. These so-called "studio" studios, in which usually about a dozen or more photographic assistants are employed, offer photographs at very low prices. This they are enabled to do because of the extent of their business and the advantage they are in buying material. From this wholesale kind of business the quality suffers, of course, and most of the photographs are of low standard. However, the low prices attract the public. The second cause we have already mentioned in a previous report. We refer to the absurdity of prices, and it has intensified meanwhile. Many even the smallest consumers at prices which scarcely yield a profit. Although the old makes of high quality still command higher prices, which are willingly paid, yet important reductions have to be made. Fresh efforts are being made to come to an understanding as to prices for the home market; but it remains to be seen whether these will be successful. In opposition to the fall in prices, there is increased cost of production. Raw materials, especially glass, are markedly dearer, and this is the case with labour. Good work-women are very difficult to find, and beginners' wages have increased at least 20 per cent."

* * *

Chantrey Trust and its Administration. For many years past there has been considerable discontent in art circles as to the way the Chantrey Trust has been administered by the Council of the Royal Academy. Francis Chantrey, it may be mentioned, left between two and three thousand pounds a year to be expended in the purchase of works of art of the highest merit, that his name might become associated with a National Gallery of British Art. The House of Lords, last week, the Earl of Lytton called attention to the subject and moved for the appointment of a Select Committee of the House to inquire into the matter, and, if necessary, to make recommendations. In his speech the noble Earl was hard upon the R.A., and said the selection of pictures, in the opinion of almost every one, was a mere by-word and a mockery, adding that a large number of the pictures purchased were small ones, worth from £20 to £50, and in twenty-seven years, with the exception of three bought from the Grosvenor Gallery and one from the New Gallery, the whole of the purchases had been from the Royal Academy exhibitions. The Trust, he said, had become a sort of prize fund for the exhibitions of the Royal Academy. Earl Lytton further said that Henry Cole had provided the gallery in which the purchases were exhibited, and they did not include a single picture by such artists as Alfred Stevens, Ford Madox Brown, Rossetti, John Hunt, Burne-Jones, Cecil Lawson, Whistler, the sculptor Legros, and many other artists. In the discussion which followed, the Earl of Wemyss defended the Council of the Royal Academy, but he admitted that many pictures had been purchased under the Chantrey Bequest which he did not like. In conclusion, he said that the Royal Academy were not opposed to an inquiry. Lord Davey, as one of the Trustees of the Chantrey Bequest, bore out the statement of Earl Wemyss as to the Trust and the manner of its administration, and said it might encourage British artists by purchasing pictures of promising but young unknown artists. Other noble lords spoke, and in the end a motion was agreed to, and a Select Committee is to be appointed. It is to be hoped, therefore, that good will result. When such a handsome sum as between two and three thousand pounds a year is at the disposal of the Trust for the furtherance of British art, it is most desirable that the money should be expended to the best advantage, consistent with the wishes of the generous bequeather.

Personal Reflections.

There is one phase of popular photography which most persons are apt to lose sight of entirely, we mean the good service it does in making people use their brains more than they otherwise would. A man buys a camera, and unless he be of the button-pressing-and-somebody-else-to-do-the-rest species of humanity, he is bound to inquire into the why and wherefore of everything concerning it. He gets a little knowledge of optics, of chemistry, of art principles, and so forth. The great mass of people know nothing of these things, and if we read the newspapers we shall find constant evidence of this melancholy fact. Here is a recent instance. At one of the police-courts a man was accused by his neighbour, who is a dentist, of indulging in what is described as an extraordinary form of annoyance, and the assistance of the court was invoked to put a stop to it. The neighbours happened to be on unfriendly terms, which is by no means an uncommon case, and the dentist's neighbour hit upon the following device for showing his unfriendliness to him. "He had been able with the operation of large mirrors, standing in position in the back garden, to observe the movements of Mr. —'s household, and more especially what went on in that gentleman's study and operating room." The result of the application of the complainant's solicitor was that a warrant officer was sent to expostulate with the offender upon his childish conduct, and we may suppose that the annoyance has ceased. But we are inclined to believe that a great deal of the complaint was imaginary. Any one who knows anything at all about the laws of reflection will know that a man standing in a back garden could see much more of his neighbour's doings by means of direct vision than he could by the aid of mirrors. We can certainly imagine a case where a window was too high up for an observer to look into, but even then it would be far more simple to get a ladder than to fix a large mirror at the correct angle upon an aerial platform, without which it would be useless. Further, we cannot imagine that any one in his sober senses would have the remotest wish to look into a dentist's sanctum at the time he was engaged therein. Most persons have a wholesome horror of anything which reminds them for a moment of an enforced visit to one of these gentlemen, whom we all regard with great esteem in their private capacity, but assiduously hate in their professional guise. We could well understand the dentist's annoyance if his neighbour had flashed unmeaning heliographic messages into the atelier, which, of course, could easily have been done with a very small piece of looking-glass, but here we are confronted with the difficulty of "large mirrors standing in position in the back garden." We feel convinced that if the magistrate, or the solicitor, or one of the other persons in authority, had been an amateur photographer, and had had just a little optical knowledge, this bubble would have been pricked before it was allowed to make its appearance in public.

THE Ipswich Camera Club, which was founded only in March last, has had a very successful season, so much so that the committee have decided upon a two day's exhibition of pictures in the autumn, and have engaged the Art Gallery, Ipswich, on November 15th and 16th for that purpose. There will be an open section, divided into four classes, as follows:—(1) Landscape, seascape, and river scenery. (2) Figure studies and animals. (3) Architecture. (4) Lantern slides (sets of four). In each of these classes a silver and bronze medal will be awarded. The section restricted to members of the club embraces seven classes for enlarged and direct prints, and there will be presented seven miniature silver medals and seven miniature bronze medals. Full particulars may be obtained of the Honorary Secretary, 37, Henley Road, Ipswich.

THEATRICAL PHOTOGRAPHY.

FROM the rapid increase of the number of playhouses in London and its suburbs during the past few years, we may assume that theatrical enterprise is much encouraged, and that the stage and all that belongs to it is a centre of attraction to a goodly number of persons. This is further evidenced by the voluminous critiques in the newspapers of any new play, a column or more being often devoted to the subject, while some event which may affect the lives and happiness of a great number of human beings, a tragedy in real life, is passed over, perhaps, with twenty or thirty lines of type. The illustrated weeklies are not slow to follow the lead of the dailies, and it is not uncommon to find in these publications photographic reproductions of stage scenes, or of groups of actors, or single portraits of those who take the principal parts. For our present purpose we embrace these pictures under the term "Theatrical Photography."

It must be admitted that most photographs taken on the stage of set scenes with actors in position are very far from being satisfactory in every way. The art editor of a newspaper, through whose hands hundreds of photographs pass every week, said in our hearing that he had never yet seen a decent photographic reproduction of a theatrical scene. He complained that all the important details were glaringly exaggerated, the expressions on the actors' and actresses' faces were lost, and the shirt fronts of the former were the most prominent features of the pictures. It may be worth while to endeavour to discover the reason why such photographs should meet with this strong denunciation.

There are, we think, several reasons to be deduced for this failure of the camera to give a satisfying picture of a theatrical scene. First, we have the colour difficulty, and although this could be overcome by the use of a screen and a properly prepared plate, the time of exposure would be so prolonged that the inclusion of figures in the composition would be next to impossible. The next great difficulty is found in the method of lighting the stage. Scene-painters depend for much of the beautiful effects which they produce upon the judicious lighting of the various parts of their work. Lights are cunningly hidden behind wings, ground pieces, sky borders, etc., and without such aids half the pictorial effect would be lost. In a first-class theatre the lamps, which of course are of the electric-incandescent kind, are in triplicate—white, red, and green—and either white or coloured light can be cast upon different parts of the scenery in order to obtain the effects desired. But when a photograph is demanded, coloured light is switched off, and the whole stage is flooded with as much white light as it is possible to pour upon it, often with the additional aid of the magnesium flash. The pigments of the scene-painter are in this way submitted to an ordeal never contemplated by him, and tints which beautifully blend with one another under normal conditions are rendered crude and antagonistic, so that they stand out with a hard relief which is most disagreeable to the beholder. The photograph, in fact, gives much the same result as if the artist had been restricted to the use of black and white, without the power of softening or modulating either.

Another cause for the artificial appearance of a photograph taken on "the boards" applies chiefly to scenes of a domestic character. The size of the room or other place represented is necessarily measured by the space available on the particular stage upon which the play is mounted. At a large theatre the proscenium opening may be 50 ft. or more. This would be admirable for the interior of Aladdin's palace, but when the same area is devoted to the humble cottage home to which Claude Melnotte carries his astonished bride, it "fits too much." We lose sight of

the incongruity in the interest which the action of the play arouses, but it is there all the same. But the camera is quite insensible to such considerations, and it depicts the scene with merciless brutality. The characters look like tiny dolls set in a large and rather remarkable warehouse and the most noteworthy feature about them is that they are strongly lighted from the front, whilst the painted background, of a chastened and subdued quality, streams in at the lattice window at the back.

Yet another obstacle to artistic effect in these stage pictures which the camera intensifies is the straightness of the floor. This is obvious enough in an interior scene such as that just described, where the space is far too great to be broken up by tables and the little knick-knacks which fill up the chinks and corners of a room in real life. There is the straight line formed at the top of the footlights at the immediate base of the picture, and this is duplicated a few feet back, where the canvas sheet touches the floor. In a landscape scene these hard lines are fatal to picturesqueness.

We thus see why, in the souvenirs which it has become the fashion to give away to an audience on the one hundredth performance of a play, the pictures, generally admirable in quality, are not photographs of the scenes taken on the stage, but are from drawings. Excellent examples of such work were found in the souvenirs of many of the Shakespearean revivals by Sir Henry Irving at the now defunct Lyceum. But it is now becoming more the custom to make the theatrical souvenir contain a series of portraits in character of the various performers taking part in the piece. And the same wise course is being followed in those periodicals which have become so numerous of late years, which give their patrons a pictorial record of any new play which is produced. The scenes as a whole are ignored, the characters being photographed, by skilled hands, in groups. And the fewer the members of the group, the more satisfactory generally is the resulting picture. As all photographers know, it is far easier to tell a pictorial story—unless one has the brush of a Hogarth—with two or three figures than it is with half a dozen or more. And there is this enormous advantage in limiting the numbers: the picture may be taken, not on the open stage, but within the more convenient boundaries of the photographic studio, where the lighting is under strict control, and where the painted canvas is not.

One of the best of the illustrated theatrical publications is our Parisian contemporary, "L'Art du Théâtre." Printing, paper, half-tone blocks, all are of the best, but we find here the same faults as those to which we have already adverted. The scene-painting is no longer protected by the soft-toned lighting for which it was intended, and the photographed reproduction depicts it as hard, patchy, and unlike reality as possible. It may try to hold the mirror up to nature, but the photographed reflection plays it false. It is only fair to say that these remarks apply only to the pictures of set scenes, the portraits and groupings by the Parisian photographers being beyond reproach.

The most striking scenic effects are produced when, as in a painting, the background is made subordinate to the crowds of figures grouped in front of it, and when those figures are skilfully disposed by the artistic instinct of a good stage manager. Many such scenes habitués of the opera house can call to mind, and here again the question of lighting is all-important, the use of the lime, or electric arc, light giving certain groups of figures the necessary relief and contrast. We cannot hope to reproduce such a scene by photography, unless we possess the power of hypnotising the entire company to make them keep as still as statues for some considerable time; for the reproduction of such a work would require all the care and time

necessary in making an effective photographic copy of an painting. If we could banish the figures the scenery could be reproduced by the tri-chromatic method—but the picture would lose all its charm.

If we turn to the back pages of one of our illustrated weeklies of two decades ago, we can find many excellent woodcuts of scenes at the theatres, and we are bound to confess that they give a far better rendering of those scenes than do the patchy photographs of to-day. The best theatrical work done by the camera to-day are ballet and variety scenes, such as we see exhibited outside the Alhambra (not that of Granada, but its namesake in Leicester Square). Perhaps the reason for this is that we are not familiar enough with fairyland to be hypercritical. The difference between real foliage and painted greenery is at once detected in a photograph taken on the stage, but we can only compare painted fairyland with other paintings of fairyland and we have not sufficient knowledge to pass an opinion on it.

AN INQUIRY CONCERNING PHOTOGRAPHY AS A BRANCH BUSINESS OF STORES.

[Translated from the "Photographische Chronik."]

We are induced to give our readers a translation of the following report, which may be of value in estimating the extent of a recent phase of commercial competition which has excited much feeling amongst German photographers:—

From the report which appeared in No. 3 it will be seen that the members of our Association at their last year's meeting

Berlin ordered an inquiry to be made concerning store photography, and the Association of German Photographic Assistants concurred in its desirability. It was to be expected at such an inquiry—like most others of a private character would not give a complete picture of the relations which exist in the store photographic business. For this reason the Photographic Association of Berlin spent some time in trying to induce the Minister of Commerce to direct a return to be made giving the desired information. But this could not be conceded, and the Association was directed to take suitable steps to obtain for itself the particulars sought for.

The presidents of the State Association of German Photographers and the German Photographic Assistants' Association constituted a commission, and the following results have been deduced from their work, which has just been completed. Of the question sheets which were sent out to business houses, 49 with answers were returned from 18 towns, whilst those sent to employes at the departments of stores 160 were returned answered.

The 49 stores in question had in their photographic departments 309 employes, of whom 57 were operators, 85 retouchers, printers, and 24 general assistants; 46 were employed as helps, and there were 8 apprentices. The number of women engaged was 95. The average hours of work were 10, exclusive of breaks, and 8½, 9, and 9½ hours were only exceptional instances. The term of notice was generally a fortnight, and in only 10 to 12 cases was a month's notice usually given. Few fines were inflicted, and then only for lateness. The answer to the question "How many portraits are taken daily?" was not answered with much exactness. As far as could be ascertained, about 735 portraits were taken daily in the 49 businesses, and the average for each would be 15. But the number of portraits taken in each studio is very different; for instance, one house in Berlin, on an average, takes 120 portraits daily, whilst in other small businesses only about 8 are taken. The minimum prices for cartes-de-visite and cabinets are 1s. 9d. to 1s. 11d. and 4s. 6d. to 4s. 9d. per dozen respectively. The maximum prices vary considerably, and

range from 6s. to 8s. for cartes-de-visite and 12s. to 18s. for cabinets. In a few establishments the receptionists are paid premiums for securing higher prices and large orders.

The following particulars concerning the 160 employes were taken from the question sheets returned by them:—

15 employes ranged in age from 16 to 19 years			
71	"	"	20 " 25 "
31	"	"	26 " 30 "
15	"	"	31 " 35 "
11	"	"	36 " 40 "
5	"	"	41 " 45 "
1	"	"	46 " 50 "
2	"	"	51 " 55 "
1	"	"	56 " 60 "

Nearly half the employes who answered the question concerning their age are therefore between 20 and 25 years old. The question if married, was answered in the affirmative by 38, and in the negative by 118.

One hundred and fifty-three sheets gave an answer to the important question concerning income, and the following classification may be made:—

25s. monthly... 1	80s. monthly... 9	150s. monthly... 9
30s. monthly... 1	85s. monthly... 3	160s. monthly... 3
40s. monthly... 1	90s. monthly... 15	175s. monthly... 1
50s. monthly... 2	100s. monthly... 27	180s. monthly... 1
60s. monthly... 6	110s. monthly... 10	200s. monthly... 7
65s. monthly... 4	120s. monthly... 26	250s. monthly... 3
70s. monthly... 8	125s. monthly... 2	300s. monthly... 1
75s. monthly... 4	130s. monthly... 6	350s. monthly... 1
	140s. monthly... 2	

The average wage, therefore, is about 110s. per month. Of the 153, 10 receive the average wage, 62 earn more than 110s. per month, and 81 have to satisfy themselves with less than the average. Most of the employes, 81, receive their money fortnightly, 49 receive it monthly, and 23 weekly.

The answers concerning the hours of work, in this set of returns, agree with those received from the different firms:—111 employes worked 10 hours daily; 27, 9 hours; 8, 11 hours; 6, 8 hours; 4, 9½ hours; but only 1, 7 hours. The question, if Sunday work was required, was answered in the affirmative by 84, and in the negative by 73; 87 received payment for overtime, but 53 did not; 153 of the employes who replied named the branch of work in which they were engaged: 51 were retouchers, 36 printers, 28 operators, 16 general assistants, 16 receptionists, and 6 helps.

As already mentioned, it was not to be expected that the returns would give a complete picture of store studios, but the result would have been more complete if a considerable number of employes had not refused to answer. For instance, one of the persons to whom the sheets were confided sent the following reply:—"The filling up of these returns was absolutely refused, and the writer cannot supply the answers, as the information at his command is insufficient." This abstention is the more regrettable as the greatest privacy regarding their identity was promised to those concerned. On the other hand it was a pleasure to see that in some cases the return had been made most conscientiously and always gave satisfactory information. This offers a splendid basis for future action.

THE annual general meeting of the Röntgen Society will be held on Thursday, July 7, 1904, at 20, Hanover Square. The chair will be taken at 8.30 p.m. The Council have arranged that the library of the Society at 19, Hanover Square, shall be open to members, for reference, every Thursday afternoon from 5 p.m. to 7 p.m. Members are invited to send to the librarian any contributions of interest—books, journals, skiagrams, tubes, etc.

THE STEREOSCOPE APPLIED TO ASTRONOMICAL RESEARCHES.

II.

LET us now examine the stereo-comparator by the aid of which we shall study the plates obtained. Fig. 10 represents the first style, such as was constructed by Dr. Pulfrich for plates 13 x 18 cm. The plates are arranged on an inclined frame-work in the form of a disc, and they may be oriented in their plane or adjusted in two perpendicular directions by measurable amounts. A bent arm attached to the top of the frame-work supports the optical part in front of the plates; it will be a reflecting stereoscope when one wishes to judge of the plate as a whole; or a binocular microscope when one wishes to study the plates in detail, and to take measurements on them. In the first case the course of the luminous rays is similar to that which takes place in the telemeter of Helmholtz. The arrangement of the binocular microscope is outlined in Fig. 10; O_1 and O_2 are the objectives, I_1 I_2 the eye-pieces of the two bent microscopes; R_1 R_2 represent the location of a system of lenses reflecting the images received from the plates

Fig. 10.

P_1 P_2 . In the plane of the images p_1 p_2 a movable mark is changed by a micrometric screw m , which comes into play in the measure of distances. The binocular apparatus is necessary to determine this; but it is evident that it also furnishes the two other co-ordinates, the height and the width of the objects; then a single microscope may be used just as in the comparators already employed for several years in measuring stellar photographs.

We now have at our disposition an apparatus which presents advantages over all the means hitherto at hand. In the first place, the stereoscope wins for itself a very natural satisfaction; look, for instance, at such a view taken in the mountains at the extremities of a base of 45 metres. What striking relief! It is true, one does not realise in examining this picture the impression of grandeur that strikes the traveller going over the gigantic contortions of the Alpine soil. By no means; one might rather imagine himself in the presence of a sculptured model, on a reduced scale, reproducing with wonderful delicacy all the details of the surface. Evidently it can be used to reproduce in relief on a small scale all the details of which stereoscopy has given evidence.

Then let us look at the photographs of the moon; they are slides obtained by Messrs. Loewy and Puiseux, and which have been combined in the stereo-comparator; they represent nearly the same phase of the moon; but it is noticed that, in consequence of the well-known phenomenon of libration, the satellite does not present to us exactly the same face. The whole appearance here is as if, the moon remaining fixed, the observer had changed his position with regard to it, by an angle equal to the libration; at the distance which separates us from the moon, this amounts to a displacement of about 100,000 kilometres in the case considered. Then bringing together in the stereoscope the two images obtained at the extremities of a base of this length, a very clear sensation of the rotundity of

our satellite is obtained. Much more, Mr. Pulfrich has been able, by the aid of the movable point in the field of the microscope, no trace on the curved surface of the moon a series of lines uniting points at the same distance from the observer and to obtain a system of curves on a level, analogous to those traced on the geographical maps and enabling us to follow in detail the structure of the lunar surface.

Let us examine in the same way the two photographs representing Saturn, including the mass of stars surrounding Ophiuchi. These two views taken by Mr. Wolf at the Heidelberg Observatory, June 9 and 10, 1899, when examined by the stereoscope give a legitimate surprise; the planet—with two of its satellites even—appears freely suspended in space very far in front of the background of the picture formed by the group of neighbouring stars, which seem, because of the immense distance, infinitely removed in the same place. Figure 11 enables one to understand the effect. O represents the sun; T_1 T_2 S_1 S_2 respectively the positions of the earth and of Saturn on June 9 and 10, 1899, a period near the time of opposition. The first day the planet is seen in the direction of T_1 S_1 ; the second day it appears in the direction T_2 S_2 . The combination of the two views in the stereoscope produces the same effect as though one were looking at the planet with the right eye at T_1 , the left eye at T_2 , that is to say, as though Saturn were at S .

Fig. 11.

In the direct view with the naked eye the base of operation is about 65 millimetres; in the stereoscopic telemeter this distance is extended to one and one-half metres; then we have seen by what arrangement this distance may be increased to 10, 20, 100 metres and even more. Finally we find ourselves enabled to use a base of more than 2,500,000 kilometres, thanks to the revolution of the earth around the sun. It is not surprising that with the eyes spread apart to such a distance one can take account of the disposition of the stars in space. Let us note also that we see Saturn not at its real distance from the earth, but at a point S farther away than S_1 or S_2 , because of the movement of the planet while the earth moves from T_1 to T_2 . If Saturn had remained motionless in the interval the stereoscopic effect would have been still more obvious.

We can examine the comets in the same manner and assure ourselves that the tail is undoubtedly turned away from the Sun; more than that, we shall have a means of gaining exact information of its structure and dimensions. For, let us note in this connection, one can effect pointings on an object with a definite outline like the image of a star, with the same ease and the same precision as on those with blunt or poorly defined outlines, such as the foliage of a tree, the smoke coming from a chimney, the clouds of the atmosphere or the nebulae of the sky. It is a fundamental property of the stereoscope; the importance of this peculiarity will be noted especially in the search for the height of the clouds, for example, when the lack of points of reference necessary for exact setting is the principal cause of the uncertainty which this study admits of with the means used up to this time; it will be equally valuable in the study of the displacements or modifications which the nebulae undergo, a field in which our knowledge is still very incomplete.

On the other hand stereoscopy furnishes a very simple means of comparison of two plates of the same object. One could examine them by transparency by placing them one over another

and find out whether certain details are not different in the two images. But this is an extremely laborious procedure and not very exact, especially when one is studying stellar photographs, for it will be necessary to pass constantly from one plate to the other to assure oneself whether a change thus indicated is real and does not result from a defect or from an alteration of the plate. Here, on the contrary, it suffices to take a glance into the stereo-comparator; at the slightest difference in the two objects, certain parts appear to detach themselves in front of the others, or they announce themselves by a trembling, an instability in the image when they are of different brilliancy or are found only on one plate. This property is susceptible of innumerable applications; we can utilise it to study, for instance, the slow displacement of a star, to prepare and verify graduated scales, characters of lighting, etc. We can also apply it to the examination of the spectrum of stars with reference to their radial velocity; the displacement of the rays by virtue of the Doppler-Fizeau principle will make them appear in planes different from the rays of the spectrum of comparison. The measures that can be taken will be much more exact than by the actual means, since the lack of clearness of the rays or bands is no longer an obstacle to the precision sought for.

We have here also a new means of attaining the knowledge of the proper motion of the stars. Until now a limited number of stars could be examined from this point of view. They are the general brilliant stars easy to observe with the meridian instruments or lending themselves to micrometric measures by their relation to neighbouring stars. But for the greater number of faint stars, for the nebulae, nothing is known as yet. It would be necessary to have recourse to photography and to measure carefully, after a pretty long interval, the positions of these innumerable stars in order to assure one's self of an actual displacement, a work which would require an immense amount of time. What have we to do here? It is enough to take under the stereo-comparator the two plates representing the same region of the heavens; if certain stars have changed their place, they will appear to detach themselves from the mass of other stars which form a flat background, as in the stereoscopic views of Saturn. This applies equally well to the small planets that can be found with the help of two photographs taken at a relatively short interval. These stars strike the eye at once on the inspection of the plate without its being necessary to search laboriously for them. It is, so to speak, impossible not to see them. It is thus that Mr. Wolf, well known for his numerous discoveries of little planets, had submitted to Mr. Pulfrich for inspection two plates on which he had recognised several asteroids after a minute comparison; Mr. Pulfrich, although entirely inexperienced in these researches, discovered at a glance, with the help of his new stereo-comparator, all the objects noticed by Mr. Wolf, and pointed out besides a new asteroid which had escaped the Heidelberg astronomer, who must nevertheless be considered the man the most experienced and the most skilful in this matter.

Finally, the variable stars will not escape the observer either. They distinguish themselves by a sort of scintillation contrasting with the tranquil and steady light of the background. They strike the eye, and even produce a sensation so disagreeable that one cannot mistake them. Quite recently Mr. Wolf published the result of the comparison of photographs of the large nebula of Orion. Thanks to the stereo-comparator he finds in it no less than twenty-four new variable stars, among which several are remarkable. Finally, the defects of the plates, which it is also very important to recognise, become evident in the same way.

Without doubt, before being able to study by this means the proper motions of the stars, and, what is still more delicate,

to determine thus the stellar parallaxes, the art of photography must be brought to greater perfection; there will be many difficulties to overcome, arising especially from the dispersion caused by the atmosphere, and from the difference in the colouring and composition of the light of the stars.

Still the different experiments where stereoscopy has been put in practice have appeared up to this time so convincing that one can hardly prophesy yet where the applications of the new method will end.

G. VAN BIESBROECK.

FADING OF SILVER PRINTS.

The fading of silver prints is a subject that is always with us, but we do not seem to get much nearer to the why and wherefore thereof. Everything used throughout the different processes from start to finish has been blamed in turn. Therefore, anything that will shed even a little light upon the subject should be useful. It has been stated frequently that the mountant has much to answer for as so many unmounted prints have been found in good condition many years after production. To determine not only if the mountant was guilty, but also if possible the part played by light and free access of air, these experiments were undertaken.

On November 10, 1894, three prints were made from the same negative, care being taken to print them to exactly the same depth. The paper used was Ilford Matt. They were toned to purple in borax toning bath, the prints were thoroughly fixed and well washed in running water by themselves, constantly moving, for two hours. The backs of the prints were divided horizontally by pencil lines into five parts, and one of these parts of each print was coated with dextrine, flour paste, starch paste, gelatine, one division being left bare. They were mounted in this way: No. 2 upon clean glass, No. 2 upon card, No. 3 upon card with the centre cut away so that the side edges only were attached to the card. The card used was a high grade one, made for water-colour drawings, supposed to be pure, bought of a good artists' colourman. A strip of card about $1\frac{1}{4}$ inch wide, wrapped in Swedish filter paper was placed perpendicularly over the centre of each, attached top and bottom, and in the case of the glass and cut-out mount, at the back as well, to exclude light. They had no cover glass or frame, but were hung to a lath close together and exposed in the lightest part of a room facing south where the sun (when he deigned to shine) would play upon them part of the day. In particularly bright and settled weather they have a number of times been hung in the open air upon a wall facing south, for days and nights at a stretch. This treatment should be sufficient to try the keeping qualities of any silver print. It did these. On May 18, 1904, nine and a half years after the mounting, the filter paper shields were removed and the prints examined. The story they tell is this: They are now not of equal strength, the print on card is the palest, the one on glass comes next, that exposed on both sides—the cut-out mount—darkest. The difference is considerable, all had faded, and they now are brown instead of purple. There was much yellowing upon the exposed parts and some on the marked portions, especially upon the one with the cut-out mount. I could detect no difference whatever in any of them attributable to the mountant. The part which had received no adhesive was most stained on each of the prints. To ascertain how much of this stain was due to accumulated dirt, etc., on the prints, cold water was let to run upon them, carefully brushing with a badger hair mop. They were then put to soak in cold water to remove them from the mounts, after removal well washed in running water, and dried. The washing removed much, if not all, the yellow stain from the parts that were covered in the cases of the glass and card mounted ones, that from the cut-out mount showing little improvement.

By transmitted light all gain a little of their original purple

tone down the strip that was covered. They are all at least as much stained where no mountant was applied as at any other part, so that it would seem the mountant, other things being equal, tends rather to preserve the print. That the free access of air is the powerful factor in the yellow staining, for the one exposed back as well as front was most stained. (On the other hand it had faded least.) That darkness does not prevent fading but to some extent preserves the original tone, and that the freer the access of air the more the print stained. Perhaps I should have stated before the print on the cut-out mount when the mountants were dry naturally buckled, the strips of card used for exclusion purposes not coming into close contact with the print either front or back, would protect it less from both light and air than in the other two cases. No yellow stain occurred when protected from light and free circulation of air. Lastly, the stain runs right through the paper. It really seems quite impossible to remove the whole of the silver compounds we do not need when we have finished our prints.

A. J. BROWN.

THE ARTISTIC ASPECTS OF PHOTOGRAPHY.

II.

It is, of course, extremely difficult to be original without cutting adrift from the moorings of good taste. In the matter of subject, every available field has already been exploited; in the matter of treatment, the dealers have offered to the million, for a few pence, every variety of material needed for the varied printing processes. Even the designers of picture frames have run through the whole gamut of styles, from unwieldy constructions at one end, to no frame at all at the other, including every material, natural or fabricated, under the sun. The man who would display originality, therefore, is driven, in the matter of subject, to subvert all accepted principles of composition and arrangement. In doing this, he finds vagaries of trimming afford him great help. A group of figures may have their top hair "trimmed" in this manner, whilst their feet and the carpet pattern hold the centre field of the noble work. A profile portrait is constantly trimmed just in front of the ear, as you all must have frequently noticed. I expect to see the day when a full-face portrait is presented by the same half measures. So far as treatment of printing goes, the efforts have been mostly in the direction of perfectly flat, and most often dark, effects upon a roughened paper that exaggerates the already too granular effect of the image. Absolute silhouettes are sometimes offered us in apparent seriousness. Who in their senses would consider it worth while to make silhouettes deliberately by photography? What does such a treatment give? One thing only—hard outline: the very thing that is anathematised by so-called artistic photographers. No tone, no planes, no "drawing," as photographers elect to say, no gradation, no textures, no atmosphere, no modelling, no detail, no quality. The original ones probably grew and flourished at Brighton; the modern ones are in place at Yarmouth. The name of an unpopular French Minister became, in derision, applied to everything cheap and trifling. How well it was applied to this form of art, and how well is it still applicable to the empty flatnesses that disgrace pictorial photography in our galleries to-day! Travelling in an opposite direction to the fatuous reaching after originality, is the equally dangerous practice of apeing certain methods peculiar to the graphic arts. I use the term "peculiar" advisedly, for the most senseless of these apeings is that of the scratchy background to a figure, which, natural, fitting, and desirable as it may be to a worker with a pointed instrument upon metal, stone, or paper, is monstrous when applied to any other form of representation, and despicable into the bargain, when it is applied to photography. I have brought with me a choice example of this precious form of Art with a capital A, which I should be glad if you would

inspect before you leave. When you have noted the scratchings in the background, the shoulders, and the hair, you will not need to have pointed out to you the utter incompatibility of it all with the photographic smoothness and absence of line in the face. Even supposing the background was of a tonal instead of a linear nature, its presence here is highly detrimental to the relief of the head. In sheer ignorance of the principles he is pretending to understand, the artist, as he would no doubt have me call him, has positively produced the very opposite of the effect such a background treatment would be calculated to enhance. If I were to lay my tongue to the precise expressions that I think would properly describe this performance, you would perhaps think it advisable to remove me from this rostrum by constabulary aid.

There are other instances of artistic masquerading which you yourselves can easily call to mind. Some may be less reprehensible than others, some, indeed, may have no guilt beyond a chance resemblance to methods in the graphic arts. The flagrant example I have shown is more than enough to serve as a warning and to afford me personally a vigorous and hearty protest. Amongst other misfortunes that have come in the wake of the curse of originality for its own sake is the wanton falsity of tones. This has developed into a fashion, but of fashion particularly something may be said later on. If there is any one quality in respect of which photography can and should, excel all other pictorial methods, it is that of tonal values. Judging from many works I have seen, and some that I possess, of exquisite beauty in this respect, there is no doubt in my mind that it would be impossible to find effects of light and air, that photography could not represent with more subtlety, more tenderness, and truth than any other known method of monochrome representation. Is it, in fact, however, that each photographic picture produced, with claims to be artistic, can show a due appreciation on the part of its author of these wonderful powers possessed by photography? Do we not see year by year the same utter ignorance or disregard, which is worse, of the most obvious truths in the phenomena of light? The names of several people who have somehow or other won reputations are seen in no retiring or modest characters attached to outdoor scenes that are divisible into scarcely more than two tones. In another place I have observed that tone in a naturally lit scene is, in a musical sense, chromatic—an infinitely gradated gamut—that makes in its happy combinations the rich result that chords of close harmonies make: vastly different from the effect of one note in the treble and another in the bass, which is the metaphorical description of the faulty prints of which we speak. By what right are these claimed to be, and appraised to be, of more artistic value than the glossy silver-print that is correctly exposed and simply printed? Is it supposed that the gloomy Erebus is capable of more poetic import than the natural light of day, or the glorious sublimity of sunshine? If this is maintained, then the true artist, whoever or wherever he is, will on his part maintain that the poetry of such prints is a purely subjective quality in the aberrated minds of those who make them, and is a spurious quantity in the taste of such as affect to admire them. Certainly the light that they represent was never of actinic value enough to take a photograph at all, which begs the question why it ever was taken, if the actual result of the negative was less to be preferred than the ultimate result of the print. It can only be presumed that the camera was set up with the intention of getting something on the negative that would be deliberately submitted to falsification and debasement in the printing. For such a practice there is only one name. It is prostitution; prostitution of one of the most marvellous discoveries of modern science to the whim and caprice of a faddist, who utters it seriously, as art, to the beguilement of the ignorant.

This leads to another point; the manipulation of prints

ticularly those of the gum-bichromate order. That variety print, more than any other, as I have remarked elsewhere, requires the artistic knowledge and the faultless taste. In the hands of an artist it may give charming results; but it is the same time the greatest pitfall of the photographer if he is not tolerably artistic. Generally speaking, the more prints that are amenable to handwork are worked upon, the less do they resemble the negatives from which they were derived. I doubt such manipulation is of great service to the photographer who wishes to turn a bad record of midday tones into something that, by the help of a title, may masquerade as an effect of the shades of evening. Further, gum prints are capable of a certain quality of an atmospheric kind, under the glamour which the truth of tonal values often makes an unnoticed appearance. In the matter of truth of form, there is often just much error as there is in point of tone. If the photographer would insert trees, clouds, and so forth, possessed but a little knowledge, he would be cognisant of the fact that to draw truthfully the characteristic shapes of trees and clouds requires years of careful study and observation. The probability is that he could not boast of so much education; if he could he would perhaps put it to a different use. It comes out, therefore, that the manipulated print, be it murky and indistinct as it sometimes is, usually bears upon it the stamp of unconvincingness, a great crime in art. Even the partial alteration of forms already existing in a most dangerous practice; since the accidental variations of nature, strange as they may seem, are more difficult of representation than the general forms. Invention must be backed up by both knowledge and imagination, otherwise it is feeble falsehood. Looking in view, for the moment, the subject of tone, however, it will be interesting to note the words of one of the most advanced so-called impressionistic photographers of the day, Mr. George Davison. He himself has given utterance to these startlingly true words: "It is worth while noting that some of the simplest facts of light are overlooked by photographers who have been governed by the untrue and misleading conventions and dogmas concerning gradation and brilliancy. For instance, the necessity for points of the deepest black is insisted on, in order to give scope for as long as possible a series of steps up to the points of white, regardless of the fact that this black is generally much too black for the purpose in hand. A little experiment would show how light outdoor shadows should be as a rule. For instance, the darkest shadow of a door, seen at a little distance, is lighter than the shadow side of a white curtain in a room. Consequently it is of first-rate importance in landscape pictures to keep the shadows light. To repeat the impression of outdoor light the whole picture must be luminous and not heavy or dark." For my own part I will not say that here and there a little reservation might not be made as to these remarks. Mr. Davison admits to being influenced by a certain Mr. Francis Bate, of the English Art Club. That gentleman overlooks the fact, and Mr. Davison is inclined to overlook it with him, that the perfect representation of natural light, especially sunlight, involving obviously an impossibility, it becomes necessary in art to compromise, and to take nature in a key low enough to admit of something like true relations in chiaroscuro even using the whitest paper as the brightest spot in the picture. This necessarily places the shadows rather low in the scale. Nevertheless, Mr. Davison's words are, as I have already said, remarkably true. They were spoken more than four years ago. Are they borne fruit? Not a whit! Truly photographers are a stiff-necked generation! We see plenty of sunlight pictures veritably as black as ink, wherein the evidence of actual sunshine exists nowhere but in sun-cast shadows which are darker than ink, unless perchance the print is made in Indian or emerald green.

I do not deny that there are dangers in an opposite direction.

There is such a thing as the "washed-out" print which is perhaps the outcome of the principles advocated by Mr. Francis Bate, to whom Mr. Davison has expressed his own indebtedness. It must be nearly twenty years since I read the little pamphlet in question, but I remember enough to know that it advocates light shadows everywhere, so that the whole picture may be suggestive of light. A picture so executed would, in itself, undoubtedly be fuller of light paint than one painted with plenty of shadows in their true relations, giving a truer sensation of actual daylight. And a peasant, who confronted it might find himself somewhat dazzled, as he is when the sun shines in his eyes across the fields. But this effect upon the spectator is, I hold, an illusion, a trick. It is magnificent; but it is not art. There is another question which is always fruitful of discussion. There is scarce need to name it. I refer to definition and diffusion of focus. To myself I put the case shortly thus: Given every other particular and circumstances good and perfect; which photograph should I prefer, one with keen definition or one with wide diffusion? I should not hesitate to choose the former. Perhaps you will say that I seek "a poor choice in rotten apples," and that the wise selection lies midway between the extremes. This may be granted, but it avoids the point. If it could be proved instead of merely claimed that wide diffusion is productive of more artistic results, no one would hesitate of course. So far as I know, it has not been proved, and hence the supporters of the method are still in the minority. Let us ask ourselves whether this diffusion of focus improves what photographers call "drawing." Who has the temerity to say that it does? Does it improve the modelling? No more than the "drawing"! Does it facilitate the representation of textures? Scarcely. Does it secure tonal values? The very reverse can be proved. Does it produce breadth? Yes, of that sort that it is better to be without! Clear definition, on the other hand, may be shown to be necessary to the perfect portrayal of delineation, modelling, textures, and tones. It may further be demonstrated not to stand in the way of breadth, whilst it certainly is an added truth.

It is claimed that diffusion of focus renders a scene more as the human eye beholds it, but it is difficult to follow and endorse the arguments of those who advance that claim. Much easier is it to demonstrate that the human eye in a healthy condition never saw a scene blurred all over. Should I be thought too presumptuous if I directly combated the favourite theory that the eye only sees one spot sharply and all the rest blurred? I grant that one spot is seen distinctly, but I submit that the vision flits so rapidly and adjusts itself so instantaneously that all parts of a scene are, to the eye, definitely viewed. Moreover, there is scarcely any need of what is known as "accommodation" in viewing things beyond the distance of, say, 50 ft. and right away to the horizon. Take, for example, a line of elms in winter time that stand against the sky at the farthest distance. A diffused focus will melt their forms away to nothing, but the eye will retain them perfectly. They are soft, of course, but sharp, nevertheless. It is the greatest blunder to suppose that an object may not be soft and yet have sharp edges. Distance affects tone only and solely. It has practically no effect whatever on sharpness. A notice board may be unreadable at a certain distance, but what renders it so? Are the letters blurred? Certainly not. Lift the veil of the atmosphere, as can be done by placing the board in a climate of clear air, and there are the letters, legible enough. When photographers learn the difference between veiling and blurring, we may have fewer fuzzygraphs. I am prepared to go a step further and maintain that although the eye only dwells definitely upon one small spot, all that it sees, more and more indistinctly, around that spot is not indistinct because it is blurred, but because it is fainter throughout. The retina is sensitive everywhere, though mostly so at one point. Correspondingly we see brightly at one point and more faintly over

the rest of the field of vision. Diffusion is another means of escape for truth of tone. The less definition, the greater the falsity of tone values. A picture thrown upon a lantern screen and turned more and more out of focus will show the tones going more and more out of key until the whole is a general grey mass. Our enlargements almost always suffer in tonality upon this principle.

What saving grace remains then of this so-called artistic method of photography? For my part I think it nothing more than a fashion, set going in the first place by some well-meaning individuals who thought to save pictorial photography from the stigma of hardness and harshness that had brought the early albuminised proofs into disfavour. At this day, however, there is no fear of such a stigma. The complaint of black trees, hard shadows, and white skies has passed away. Why should the drastic remedy for them remain? If we are well, spare us the nasty medicine! A less scientific consideration of this point lies in the question of breadth of effect being the enemy of detail. There are sufficient photographs about, to say nothing of painted pictures which show this dogma to have been long exploded. Indeed, it should never have been inflated, for breadth cannot be correctly defined as absence of detail. It is to be feared that fashion is too strong a factor in the photographic world, wherein imitation seems to be the sincerest form not of flattery, but of enviousness. The need of taste becomes more urgent than ever; whilst the supply of that need appears to be weaker than ever. Individuality of taste bids fair to be swamped in a blind following of fashion, whilst fashion in turn has a tendency to become more and more independent of taste. This is the deplorable fact in modern pictorial photography. There is no harm in the natural evolution of styles which flow in one direction for a period and then turn into fresh channels. But it is without doubt lamentable to the last degree that an art, or a craft (what you will), proving itself daily to be the deepest and widest influence in pictorial affairs that ever urged over mankind—an influence so insidious, so irresistible, that it has even undermined the most cherished traditions of art—is lamentable that so powerful an influence should not exist with less downright and wanton opposition to the most obvious truths of nature, and, in the matter of arrangement and design, less disregard of those logical and rational progressions of thought that are common to all sensible people of whatever race and age.

The worst form of fashion is that which does not pass or change, but which crystallises into a convention; and photography is threatened to-day with worse conventions than any of the older ones of artistic origin. Fashions that are more upheld by individual vanity than changed by individual taste are disastrous indeed. Under their potency the evolution of photography is pushed and pulled by activities that have more of moral delinquency than artistic single-heartedness. Although there are many men of well-formed taste to stem the tide they are yet too few. The masses gladly follow this tide because to their understanding no wiser course is apparent. They are imitative and therefore lack even the individualism of the leaders whom they think it politic to follow. Thus it comes about that the workers of second rank who fill our exhibitions and magazines display a deal of manner to a modicum of matter, preferring to be fashionable at second hand to being at any rate freshly natural. Sad as all this is, it is remarkable that there seldom appears any protest against the senseless and uninteresting prints that are made and popularised in the name of photography and art. Critical acumen is at a low ebb, and so "anything will do." It does the better too if folks cannot understand it. The reason for this unconventional plain manner of speech on my part is this: I am convinced of the possible beauties of pictorial photography and am deeply interested in it. My own little collection of photo-

graphs, taken by some of my friends, are as choice a set of pictures as any artist need wish to see. In face of these facts it is painful to meet with so much that is of a lower standard coming from hands that should do better. Had I not known what beautiful work is possible within the bounds of good taste I should perhaps have declined the much-esteemed invitation to speak to you to-night. It seemed to me, however, an opportunity to place on record a protest against the trend of the indiscriminate admiration which seems to be growing for works that are distinctly not clever, and not in good taste.

The panegyrics that appear in the Press directed to the work of this or that person, who has succeeded by hook or by crook in being original, has become nauseating. This and other practices put a premium on certain kinds of work and decide the unwary to follow the same path. Sooner or later it will be found that it is a path that can only lead pictorial photography into the contempt of the greater world. It would have done long since but for a few dozen that recognise the claims of good taste. The newly Affiliated Societies all over the country should induce the belief in their members that correct exposure even on a shiny silver-print, is more artistic in every aspect of the case, than the scored sack-clothed expanses of meaningless pigment that parade as art. The roughness of a paper cannot possibly have anything to do with the real intrinsic art of the subject. It has much less to do with it than even the framing and mounting. To set great store by the mere grain of a paper and to count on its enhancing the artistic claims of a picture is nothing short of ridiculous. If the picture is good it will look well on glass or ivory. If it is bad, on the other hand it would probably look less bad printed on some surface having the texture of a well-decayed stone wall. The texture of the mere support is purely a matter of scale. We do not find miniatures on coarse canvas, and we should not look for frescoes on polished ivory. The plea that a strong texture breaks up detail is a confession of weakness. Detail properly rendered is not in want of breaking up. More often the reverse advantage, if any, is that much roughness breaks up an unduly exposed tract of smudge that would be unbearable in a smooth platinum paper.

In conclusion, I must beg you not to think that my remarks are intended to be sweeping. The delinquencies I have referred to are, I admit, often exceptional cases in a series of work from one author; but their occurrence none the less perhaps the more gauges our ideas of his taste. Good taste is what I urge as the salt of good photography. F. C. TILNEY.

SOUTH ESSEX CAMERA CLUB.—A fortnight's trip to Belgium, starting on August 6th, at an inclusive cost of £5 10s., is being organised by the president (Mr. Walter D. Welford), and it is open to members of other societies and lady and gentlemen photographers and their friends. Headquarters will be at Bruges and Brussels respectively, and among the places to be visited are Antwerp, Ghent, Namur, Dinant, Liege, Waterloo, Ostend, Malines, etc. Full particulars may be had from the President, at Warwick Lodge, 166, Romford Road, London, E.

INDECENT PHOTOGRAPHS.—At a meeting of the Glamorgan County Council, on June 23rd, a letter was read, stated to have been received from Merthyr at a public meeting, at which place it was suggested that the County Council should seek powers in Parliament to make a bye-law prohibiting the sale of any indecent photograph. The chairman said he had received a great many resolutions upon this subject passed at different places. As he understood the matter from the Clergy they had no power to make bye-laws which were contrary to the common law. The National Vigilance Association seemed to think that the law was not strong enough. Consequently that was a matter for Parliament and not for the County Council. Alderman Llewellyn moved that the matter be referred to the Local Government Committee who might possibly devise some bye-law that would be applicable. The resolution was adopted.

THE OPTICAL PROPERTIES OF DEVELOPED LIPPMANN EMULSIONS.

Following interesting abstract of a paper published in the *Zeitschrift der Physik*, by Ferd. Kirchner, appears in the *deutsche Photographen Zeitung*:—

The author's investigations relate to the optical properties of the grainless emulsion required for the Lippmann process, the properties may be of considerable importance in the correct rendering of colour. The Lippmann plate, unlike the ordinary black negative, shows a pronounced colour. By transmitted light it may be brown-red, green, blue, or, in fact, any colour of the spectrum. According to the author, colour is dependent upon the kind of developer used, and the fineness of the grain of the silver bromide. With the pyro-sodium bromide-ammonia developer, the characteristic brown-to ruby-red Lippmann colour is always obtained, and with some certainty olive to grass-green may be secured with iodol. By using metol instead of pyro, brown tones, with an admixture of blue or violet, are sometimes obtained. Frequently with this developer the colour is pure blue or violet, especially if the metol solution be old. The author only succeeded once in getting a blue tone purposely, not accidentally, when he used a very old, brown metol developer. Plates perfectly free from grain give red or brown coloration with the greatest certainty, but if the grain is so coarse, that the film may be clearly seen upon the glass, then this colour is obtained with ease. The author has also observed that Lippmann plates in the wet state possess less absorption than in the dry state, and that there is a change of colour in most, especially the blue. The author has also established that exposure brings about a swelling of the gelatine (from 1 to 2 per cent.); not a shifting of shade. Without entering upon the very numerous questions which have been so carefully investigated by the author, and which have great interest in theoretical physics, but which are unimportant to the readers of our paper, we will merely add that the author has determined the quantity of silver in a Lippmann emulsion. As the quantity of silver present is extremely small (about 1 m.g. on a plate) it could not be done in the usual way by chemical analysis. The visual method had to be employed, by taking a standard solution of silver as a means of photometrical comparison. It was found that the quantity of silver present represented one-three-hundred and eighteenth part of the total volume. If the whole of the silver on the plate were collected in the form of a single film, this would represent one three-hundredth part of the entire thickness, in round numbers. As the prepared emulsion, according to the formula supplied by Neuhaus, contains silver to the extent of one-hundredth of its bulk, it would appear that about one-third of the disposable silver is deposited during exposure and development. In conclusion it may be mentioned that the author looks upon the change of colour, referred to above, as a kind of vibratory action. Upon theoretical grounds he thinks it probable that the supposed vibrators are particles of silver composed of groups of molecules analogous to colloidal solutions. The size of the gold particles is known with approximate exactness from the treatise published about a year ago by Siedentopf and Zsigmondy."

A New Developing Formula.—Mr. A. L. Henderson introduced a new formula for a developer at the London and Provincial Photographic Association last week which gave rise to much discussion. The developer consists of:—No. 1: Hydrokinone, 120 grains; metol, 10 grains; adinol, 30 grains; soda sulphite, 2 oz.; water, 20 oz. No. 2: Soda hydrate, 120 grains; gelatine, 40 grains; water, 20 oz. or use mix equal parts of Nos. 1 and 2. Mr. Henderson claims that the gelatine acts as a mechanical restrainer, and that if detail is now in appearing rubbing with the finger-tip will bring it out at once.

PHOTOGRAPHY AS A PROFESSION IN THE UNITED STATES.*

FIRST ARTICLE.

BEFORE I had sat very long in the editorial chair I became very interested in the professional and his work. Somehow or other I got so close to many of them that they felt they could tell me their troubles, their aspirations, and their failures, so before long I began to realise that while it was very congenial employment for a great many people, the occupation of a photographer brought to the average man a very meagre living. In the past six months I have made it my business to probe deeply under the skin, and from actual figures I find conditions to be just as bad as I feared. To make sure of my ground while speaking before a recent convention, I made the statement that I believed that at least 75 per cent. of the fraternity, whether employer or employee, did not have an annual income exceeding \$500, and urged my hearers to contradict me if I was wrong, but it was admitted unanimously that my figures were correct. A good photographer is more than an ordinary skilled labourer. His occupation borders so close on the artistic that it is incumbent on him to be a man of culture to a greater or less degree. In the daily routine of business he meets people who are in their best clothes, and so must dress at least decently. His business calls, therefore, for many little expenses, costly tastes and habits unknown to most business men, and yet the profession as an income-producer has fallen so low that the average man gets out of it a sum that is equalled only by the ordinary day-labourer. While an ordinary mechanic can command from \$3 to \$4 a day, photographic employees are offered—and here I know actual facts—from \$8 to \$10 per week, with seven days' work at that. Only once in the past six months have I known of \$20 being offered, and this was to induce some one to go to a city in the desert plains of the South-West.

The social status of the professional photographer is a decidedly unsatisfactory one. As a professional man—he ordinarily claims to be that—he is decidedly the lowest rung in the social ladder, while as a business man he ranks alongside the village barber. In plain English, his calling does not at present demand from him a sufficiently high education to entitle him to social status equal to what is granted the doctor or lawyer, while his financial condition forbids him ranking with the grocer and hardware man who may be his inferior in scholastic attainments. It is all very well to quote the much-hackneyed lines:—

"Worth makes the man,
The want of it the fellow,"

but in the last analysis dollars and cents determine almost everything. It is money that makes possible the college diploma in the doctor's hand, and it is the same coin that makes the tradesman an influential man in his community. The tramp has no social standing because he is entirely deficient of funds, the millionaire is good enough for any society.

After all, what constitutes a profession? It is an occupation into which entrance is difficult to the average man because those in it demand a long and expensive preliminary training from such as desire to join its ranks. Pretence is persistently made that the barrier is raised to protect the public from ignorant practitioners, but I must frankly confess that to me they are simply glorified trades unions. The mechanic, being unable to make the specious plea of the doctor or preacher, and not having the audacity of the lawyer, is forced to admit the bald truth that he is fighting for self-protection when he combines with his fellows to limit the number of apprentices, and so gets condemnation from the professional who has been in-

* We are indebted to our esteemed confrère, Mr. F. Dundas Todd (editor of the "Photo-Beacon"), for a vantage point of his series of articles on this interesting subject.

genious enough to devise an automatic method that has State authority back of it.

Barriers round occupations are as old as history. The witch-doctors of our savage ancestors confided the sacred mysteries to only a few, so that they should not be more numerous than the community could afford to support. In the same way, the Hebrews made the priesthood a family affair, limiting it to the tribe of Levi, and so automatically kept the number within bounds. But it is needless to follow history and show how the nobility of Europe limited commissions in the army to those of blue blood, how in turn preachers, lawyers, doctors, dentists, and in this country only a few months ago accountants have got legislatures to pass laws prohibiting individuals to practise certain occupations unless granted certificates of qualification by those already earning their living in it.

Photography, since it is not a profession, has no protective training course; not being a trade, it has no prohibitive apprenticeship system; not being a business, it needs no large capital in the hands of the novice before he can start out on his career. It is a free-for-all occupation into which may come the derelicts and rejects from all the professions, the scabs of the trades unions, and the unskilled labourer who cannot find a resting place in the turmoil of the industrial world. It is the haven of refuge for the destitute one whose friends get rid of him by clubbing together and set him out on a new career in good shape by lending him from \$50 to \$100.

Charity is a mighty good thing, especially at home. There is no special reason why photography should be the only dumping ground for unfortunates, no reason that I know of why it should be a dumping ground at all. Just so long as those most interested are willing to stand this kind of thing, just so long will the outside world be willing it should go on, for it relieves them of a whole lot of undesirable people. Before scattering charity broadcast over the world, take care of yourself, your family, your occupation as against all comers. Obey the law of the jungle, which demands protection of the group in which we are interested before everything else. Photography lingers on the stays as a relic of the ancient times when business men fought the members of their own group, and the impetuous condition of the average photographer easily demonstrates how unprofitable is such conduct. It is an anachronism in 1904, for one may search the whole world over for a parallel case and fail to find it until one discovers another lot of photographers.

Truly, it is time to organise, and in next issue I will try to show how it can be done. The plan I will then give was outlined before the convention of the Illinois photographers, adopted enthusiastically, and in ten minutes \$300 was subscribed by those present toward paying the preliminary expenses.

F. DUNDAS TODD.

FREE PHOTOGRAPHS—There was an amusing case at the West Ham Police-court on Monday last when George Senior, of North Woolwich, was charged with assaulting Joseph Crabham, a photographer, of Silvertown. Prosecutor said that on Saturday afternoon prisoner, another man, and two women went to have their photographs taken. Afterwards, without any reason, accused became abusive, and hit witness. He also smashed a photograph frame. Witness denied that he was left alone with one of the young ladies, and that he put his arm round her neck and asked her for a kiss. He did not say he would take her photograph for nothing if she would give him a kiss, "because his wife was in the next room and could see." For the defence, Miss Ansell and Miss Thornton were called, and they said that the photographer put his arm round Ansell's waist and kissed her, and said that he would take her photograph free if she would kiss him. Then prisoner said the photographer was taking a liberty, and there was a struggle, in the course of which the damage was done. Eventually the accused was discharged.

ENSIGN FILM COMPETITION.

Houghtons, Ltd., have handed us the list of prize winners in the recent Ensign Film Competition. The awards are as follows:—

Class I.—1, A. E. Burnett, 31, Collingwood Road, Redland, Bristol (dealer, Tivener and Co., chemists, White Ladies Gate, Clifton); Chas. Avery, jun., 319, Queen's Park Road, Brighton (Barker Son, 319, Queen's Park Road, Brighton); 3, F. R. Sadd, care of Menement, 14, Grove Avenue, Norwich (Row and Taylor, 6, Stephens Street, Norwich); Edgar J. Richmond, Woodfold, Luton Road, Harpenden; Ed. J. Manuel, The Lodge, Westmead, Bridport; A. W. Douglas, Tantalion, Sherborne, Dorset; E. J. Richmond, Woodfold, Luton Road, Harpenden; J. Strebor, 115, Singlewell Road, Gravesend; Miss V. Godfrey, Ivy Hatch, Horsham; F. Sadd, care of Miss Menement, 14, Grove Avenue, Norwich; F. Sadd, care of Miss Menement, 14, Grove Avenue, Norwich; W. Wright, 4, Rutland Street, Oldham; F. R. Sadd, 14, Grove Avenue, Norwich; John Strebor, 115, Singlewell Road, Gravesend; H. Gidlow, 5, Wycliffe Street, New Basford, Nottingham; John Strebor, 115, Singlewell Road, Gravesend; F. R. Sadd, 14, Grove Avenue, Norwich; Dan. Dunlop, 4, Hamilton Street, Motherwell.

Class II.—1, Jas. Walker, Grange Mount, Claughton, Birkenhead (Foulkes and Co., chemists, Birkenhead); 2, J. W. Small, 8, Wynn Road, Forest Hill (G. H. and Son, Holborn); 3, Jas. H. Saunders, 76, Green Road, Burmantofts, Leeds (Leeds Photo Stores, Melbourne Street, Leeds); J. W. Small, 8, Wynn Road, Forest Hill; Fairall, 35, Lynton Street, Brighton; Miss M. Kendall, Greenheath, Kingswear, South Devon; F. A. R. Heley, 29, Casewick Road, W. Norwood; Jas. Dunlop, Myrtlebank, Motherwell; G. Slade, Mount Avenue, Ealing, W.; Miss H. Metcalfe, Metcalfe Park, Enfield, Co. Kildare; G. Slade, 37, Mount Avenue, Ealing, W.; J. Dunlop, Myrtlebank, Motherwell; Miss Hackett, Riverstown House, Birr, Ireland; W. Gundry, Hope House, Balby, Doncaster; Whittam, 6, Plantagenet Street, Cardiff; Sergeant Amir Holland, Ordnance Buildings, Crater Aden; John Oldham, 63, Hardy Street, Liverpool; B. Stoney, Portland Park, Portland, Birr; H. B. Lafford, 4, Wexford Road, Wandsworth Common; A. E. Burnett, 31, Collingwood Road, Redlands, Bristol; W. Gundry, Hope House, Balby, Doncaster; W. Gundry, Hope House, Balby, Doncaster; T. J. Hartnell, Droumhall, Killarney; J. W. Small, 8, Wynn Road, Forest Hill; Dan. Dunlop, 4, Hamilton Street, Motherwell; J. Dunlop, Myrtlebank, Motherwell; Jas. Walker, Grange Mount, Claughton, Birkenhead; Robt. Newcomb, 18, Wantage Road, Newing; A. E. Burnett, 31, Collingwood Road, Redlands, Bristol; Alwyn E. Biscoe, 375, High Road, Chiswick.

Class III.—1, A. E. Burnett, 31, Collingwood Road, Redland, Bristol (G. T. Tivener and Co., Clifton, Bristol); 2, A. M. Walter, Frothampton Vicarage, Tewkesbury (G. H. and Son, Holborn); E. R. Bull, 53, Bovell Road, Forest Hill (G. H. and Son, Holborn); Miss Jessie Peters, Harelands, Rochdale; W. J. Hodgson, All Saints Road, New Shildon; Jas. Walker, Grange Mount, Claughton, Stanley Gorse, 27, Horace Road, St. Helens; Harold Tebbitt, 2, Sidney Street, Cambridge; R. Lewis, 16, Winchester Street, Brondesbury; J. B. Meldrum, Eversley, Durham Road, Bowdon; Miss Peters, Harelands, Rochdale; W. Sharp, West View, Hensingham, Whitehaven; Otto Brown, 14, Dennis Road, Eastbourne; Miss M. Gibbings, Selsfield, East Grinstead; A. McGoogan, 31, Windsor Road, Rathmines; W. Reddam Drinkwater, Kirby, Isle of Man; John Oldham, 13, Hardy Street, Liverpool; H. C. Leat, 2, Richmond Street, Tottenham, Bristol; Edgar R. Bull, 53, Bovell Road, Forest Hill; E. R. Bull, 53, Bovell Road, Forest Hill; T. K. Yardley, 6, Victoria Road, Margate; T. K. Yardley, 66, Victoria Road, Margate; J. Hayward, 14, Albert Terrace, Whitehaven; H. J. Saunders, 6, Green Road, Burmantofts, Leeds; Miss Blakeley, 12, Parkhill Road, Hampstead; F. J. White, 13, Trogin Road, Clapham Road, S.W.; Miss L. Brocklebank, Roughwood, Chalfont Saint Giles; Miss L. Brocklebank, Roughwood, Chalfont Saint Giles; H. C. Leat, 2, Richmond Street, Tottenham; James Seeds, 137, Cavehill Road, Belfast; A. E. Burnett, 31, Collingwood Road, Redland.

Class IV.—1, James Walker, Grange Mount, Claughton, Birkenhead (Foulkes and Co., chemists, Birkenhead); 2, Miss W. Finlay, 17, Penbridge Gardens, W. (A. P. T. S., New Bond Street); Mrs. Swainson, Woodside, Brecon, South Wales (G. H. and Son, Holborn); Miss C. Gillespie, 10, Marlborough Road, Richmond.

rt Smith, Ripley Terrace, Mount Pleasant, Batley; Miss M. T. Thuxton Rectory, Allensmore; V. C. Baird, Broughty Ferry; F. V. Baird, 80, Mill Road, Motherwell; Jas. Knight, 1, Street, Wells, Somerset; Miss E. S. Mead, 14, Kensington, S.W.; Herbert Smith, Ripley Terrace, Mount Pleasant; Robt. Smith, Woodville, Longridge, near Preston; E. G. Lawrence End, near Luton.

APPARATUS FOR PHOTOGRAPHING THE BACKGROUND OF THE EYE.

WALTHER, THORNER, of the University Eye Clinic at the Royal té in Berlin, has recently succeeded in solving a problem that long occupied the minds of oculists, many fruitless attempts having made heretofore to find a solution. His invention is an im-
not one, and is a big step forward in the treatment of eye dis-
Dr. Thorner has devised an apparatus, by means of which it become possible to photograph the background of the eye and a good pictures of the same. His contrivance constitutes a rial improvement of the ophthalmoscope invented by Helmholtz 50, which latter device only admits of looking at the background e eye. Owing to the peculiar construction of the eye, it has impossible heretofore to photograph the interior or back of the It is a matter of great difficulty to illuminate the interior sufly to take a serviceable picture, and even if strong sources ht were used, the exposure would last too long, rendering neces- a fixation of the eye, which, in turn, would entail serious in-
inience to the patient.

means of his apparatus, Dr. Thorner first succeeded in obtaining graphs of the eyes of animals, particularly cats. The interior e human eye being much darker than that of the cat, it required improvements to take good photographs of the interior of human with the apparatus. The result was highly successful, the ges proving perfectly satisfactory.

th the mild light of a kerosene lamp, the eye is first so focussed its back yields a clear image on the photographic plate, a tele- like focussing glass forming part of the apparatus being used his purpose. The focussing having been accurately done, and the put in, the camera itself is opened by pressure on a special and a flashlight composition ignited by means of an electric generated in a storage battery. Thereby the background of the s lighted up sufficiently for a moment to produce a good image e plate. Still, the pictures thus obtained are somewhat un- der- stood, and require special care in developing to obtain the best. A large number of such photographs of diseased and healthy have been reproduced by Dr. Thorner in his recent book, equally esting to the profession as to laymen, entitled "The Theory of Ophthalmoscope and the Photography of the Back of the Eye," ished by August Hirschwald, Berlin.

is possible to distinguish healthy eyes readily from sick ones, eye of a strongly short sighted person being, for instance, charac- ed by a peculiar ring around the sun-like illuminated centre. istists will now be enabled to watch the progress of eye diseases isorders step by step. The apparatus also permits of taking a ure of any separate parts of the interior of the eye.

Studio Gossip.

R. CHARLES SWEET is shortly removing to new and larger pro- s at 19, Battery Place, Rotherhay, N.B.

may be interesting to note, in connection with the Northampton zes, that Mr. Justice Bray, the new judge, visited Mr. Illing- h's studio at Northampton last week, and was photographed in official robes. This is the first photograph the Judge has had n since his elevation to the Bench.

R. R. LANG SMS, photographer, of Brixton Road, recently took a s of forty pictures showing the whole process of conversion to ical traction of the Brixton cable tramway. The engineers other workers on the line were very pleased with the photos, many of them bought copies as mementoes of a record tram- ing feat, the work having been accomplished in less than ten ts—three weeks under contract time.

THE PRESS ON THE "B.J." JUBILEE.

"THIS valuable journal celebrated its jubilee by the publication of a bulky double number, full of interesting articles by experts, detailing the progress made in the various departments of photography since the establishment of this paper, and with an abundance of illustrations."
—"Shields Daily Gazette."

"THE BRITISH JOURNAL OF PHOTOGRAPHY has attained its fiftieth birthday, and issued, in honour of the event, a handsome Jubilee Number. The Editor, Mr. Thomas Bedding, F.R.P.S., is to be con- gratulated on the production of such a number as well as on the regular issues of his admirable paper. All who are interested in the photo- graphic hobby will find matter of instruction and profit in this eclectic number."
—"English Churchman."

"THE BRITISH JOURNAL OF PHOTOGRAPHY issued a special Jubilee Number on June 10th, at the ordinary price, 2d., and if any of our readers interested in the art can manage to procure copies, they will find information of the utmost possible value to them. The evolution of photography is dealt with in a remarkable series of articles by specialists in the respective phases, and should be preserved by those who are interested in the work. The articles dealing with latter day association of photography with periodical literature are specially interesting."
—"The Lady's Gazette."

"THE issue of the BRITISH JOURNAL OF PHOTOGRAPHY of June 10th is a special number, marking the jubilee of the foundation of the journal. It contains 'thirty articles on the most popular and modern phases of modern photography,' written and illustrated by authorities on the various subjects dealt with; those on 'Entomological Photo- micrography, Copying, and Stereoscopic Photography' may be spe- cially mentioned. The rapid strides which photography has made during the past half century are clearly indicated in an article by Mr. E. W. Foxlee on 'Photography Fifty Years Ago.' Both those who use photography in their daily calling and those who look upon the art as a hobby will find many useful hints in the varied contents of this jubilee number."
—"The Lancet."

"THE BRITISH JOURNAL OF PHOTOGRAPHY has just completed its fiftieth year. To mark this occasion, the Editor has issued a special (jubilee) number of the journal, containing not only 'the story' of the journal from its commencement to the present time, written by himself, but a series of most interesting articles by different authors on a great number of photographic topics. THE BRITISH JOURNAL OF PHOTOGRAPHY is the outcome of the photographic energy displayed in Liverpool in the 'fifties, the first number, entitled the 'Liverpool Photographic Journal,' appearing on January 14, 1854. In the 'story' are given facsimiles of the title-page and the first page of this journal, and also that of the first page under the present title. Short biogra- phical sketches of the editors and assistant editors are also included."
—"Nature."

"Fifty years ago is a far cry in most matters, and particularly so in those photographic. True, the period does not comprise the whole history of our beloved art; but it does cover some of the most important of the developments of camera work as we now know it. Half a century ago photography was a mere pastime; to-day it is a giant of power and potentiality. Interesting is it, therefore, to note that the BRITISH JOURNAL OF PHOTOGRAPHY last week published its Jubilee Number, an issue full of matter of comparison and information on things that concern us all. There is little doubt that the old "B.J.," as it is affectionately styled by camera men generally, has done great and glorious work in the advancement of photography, especially as a science. Optics, the chemistry of photography, the construction and perfection of apparatus, have all been exhaustively treated by experts during its long and prosperous career, and it is good to see that in the prepara- tion of this jubilant jubilee issue some of the chief workers of the day, many of them old-timers in the best sense of the word, have been en- gaged. Perhaps a few of the names may be obscure to those who have recently taken up camera work, and who are dazzled with the achieve- ments, skilfully advertised, of men who figure most in bizarre photo- graphy; but, taken as a whole, the makers of this remarkable number are readily recognised as workers who have done much to add to our knowledge of the possibilities of the camera, and, what is of equal moment, are still labouring whole-heartedly for the common- wealth. I feel that I must acknowledge my own obligations to this great cloud of witnesses to the truth that does prevail in photography,

associated, as I have been, with some of them for more years than I care to count. The BRITISH JOURNAL OF PHOTOGRAPHY does not usually call in aid illustrations of its excellent matter; but in this number we have a welcome departure from the old order of things, and galore of portraits of acknowledged leaders in photography, with occasional specimens of their work. It is to be hoped that before the centenary of the journal is reached, pictorial illustrations will be frequent in its pages; and, if the new order of things can be inaugurated now, so much the better for photography! Every amateur should secure a copy of the Jubilee Number, and find therein much of refreshment in his pilgrimage."—"Vanity Fair."

THE "B. J." JUBILEE NUMBER.—SOME MORE READERS' OPINIONS.

"All congratulation on the ever-verdant 'B.J.P.' green issue—a great success."—G. WATMOUGH WEBSTER, F.C.S.

"Heartly congratulations on the success of the Jubilee number of the good old 'B.J.'"—F. MARTIN DUNCAN.

"It is not too late to compliment you and your staff upon the Jubilee Number."—CHARLES R. ROVE.

"My hearty congratulations on the Jubilee number of the 'B.J.P.' which I have enjoyed very much."—CHARLES SWEET, Rothsay.

"Allow me to congratulate you on the issue of the Jubilee number of the BRITISH JOURNAL. My firm have taken the BRITISH JOURNAL from its first number, I think, and the publication has a splendid record."—W. D. VALENTINE (Valentine and Sons, Ltd., Dundee).

"For the past fortnight I have been waiting for an opportunity of congratulating you upon the success of the 'B.J.' Jubilee number, but this I now do most unreservedly, for probably never before in the annals of photographic journalism has it been the good fortune of an editor to offer so interesting a production to his readers."—JOHN A. HODGES.

"May I offer my congratulations on the pronounced success of the Jubilee number? Nothing could be more interesting than the historic retrospect, carrying the mind back to those old days of the 'dipper' and the silver bath, when photography was in its infancy, but still had, as a guide, philosopher, and friend, the same trustworthy mentor, then as now—the BRITISH JOURNAL!"—A. LOCKETT.

HOUSE EXHIBITION AT THE ROYAL PHOTOGRAPHIC SOCIETY.

Probably the most convincing answer to scoffers at the gum bichromate process will be found in the house exhibition of work by Robert Demachy, now open at 66, Russell Square. Granted, we are not all fortunate enough to be Robert Demachys, but still sufficient proof is put forward by this master of the one process in photography wherein the personal equation is in greater evidence, to convince the most sceptical that in capable hands the gum process gives truly perfect results to suit all tastes. The fault of the English "gummist" seems to be that he regards the process as synonymous with "making a messy, dirty print," suggestive, perhaps, of a thumb-marked, badly-smearred crayon drawing. Hence the disrepute into which it has fallen. There are exceptions, maybe, but still the main idea is that, as the gum print *can* be manipulated to almost any extent, it is forthwith manipulated whether the subject demands it or not, totally overlooking the fact that a beautiful and delicate process is being thereby prostituted.

Again, the English gummist seems also to have got the idea into his head that any negative is good enough for a gum print. In other words, if the artist (!) has a negative that falls short of perfection for any other process, he thinks it will serve for a gum print. How often have we seen gum prints by English workers at the London exhibitions, obviously printed from poor, flat negatives, and then "faked" to represent "sketches" or "impressions," or even to masquerade as crayon drawings, etchings, or whatnot. This is a grave mistake. To make a successful gum print a negative is required that, in addition to portraying a good composition, is technically perfect, or at least is so good that it would give a first-class print in almost any other medium. The most casual inspection of

the pictures now on view at Russell Square amply proves. It can be seen at a glance that the prints here are from negative the very highest technical excellence, full of detail, and admirable every way. The figures and portraits reveal at the same time breadth of handling, and disclose a feeling for the charm and dignity of the human model; while the landscapes, some of them fine design and with a true feeling for spaciousness and atmosphere, as dignifies the simplest motives, are produced in a manner that betrays the thorough artist.

The first thing that strikes the beholder on visiting the exhibit is that with a very few exceptions (five) the whole of the exhibited pictures on view are in black and white. The five exceptions are in red chalk. This must be a revelation to the many English workers in gum who will persist in using dirty browns and greens. M. Demachy points out in his introductory note to the catalogue that the exhibited are produced by a single printing only, showing that it is possible to obtain strong blacks and soft half-tones without recourse to multiple prints. The proof of the pudding is in the eating, the splendid platinum blacks, with quite a carbon lustre, the delicate half-tones, perfect modelling, and lack of granularity in the results are quite in the nature of a triumphant Q.E.D.

M. Demachy further says:—"I feel convinced that the members of the Society will examine these prints without any preconceived notions, and that they will make allowance for the well-known difficulties of the process. The collection on these walls is the result of two years' work, during which I have, apart from the constant study of values and composition, bent my efforts towards obtaining strong oily blacks and mellow half-tones. No multiple printing has ever been used, and no colour added. In a few cases (specified in the catalogue) when it was felt that the negative was unable to sufficiently vigorous accents, portions of the gelatine have been thinned down or entirely removed with a wire eraser or an engraving tool. It will be noticed that the accents are thus emphasised the positive without the actual marks of the tools being shown."

To specify one or two of the prints that call for attention, particularly noted No. 53, "Portrait of Mlle. M. D." We doubt much whether any other printing process extant would give such rich and luscious velvet black shadows and beautiful half-tones. No. 6, one of the few red chalk prints, "Académie," is a triumph in its rendering of the nude, the high lights being added with consummate skill as to give the very texture of warm living flesh. No. 76, "A Marken Girl." This is a good example of the technical excellence of M. Demachy's negatives. The microscopic fineness of the detail in the lace head-dress should be somewhat of a surprise to many who have seen only the smeary results usually associated with the "gum print." No. 21, "Première Communie." This picture is the opposite extreme of many of the vigorous pictures surrounding it, and has all the quality of a delicate pencil drawing without in any way sacrificing its "photographic" quality, which, indeed, the keynote of the success of all the pictures. No. 54, "Street at Lisieux." This is a splendid architectural study, and doubt whether a better or truer effect could be obtained or equalled in carbon or platinum. All detail is retained, and yet the picture has a breadth characteristic of its producer. No. 10, "Place de la Concorde," may be regarded as almost the greatest height to which the humble snapshot can hope to attain. We have presented a well-selected moment for the exposure certainly, but the charm of the picture lies in its after treatment. It is impossible with the space at our disposal, to attempt a detailed account of the pictures. Suffice to say that they are equal to anything Robert Demachy has ever done previously, which is saying a great deal, and the present show can only serve to enhance an already brilliant reputation. The exhibition, which remains open until Saturday July 9, should be seen by everybody interested in pictorial photography, and, whether antagonistic to gum bichromate or not, venture to predict that everyone will see much that will please and surprise him, while at the same time we also predict that not a convert to this much-abused process will also follow as an even more tangible result.

MR. HECTOR MACLEAN notifies us that he has removed from Croft to Cheam Road, Sutton.

New Apparatus, &c.

Folding Scout Hand Camera. Made by Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.
neat little camera, the latest addition to the already large of folding pocket cameras, takes pictures on roll films size 3½. The model is a great improvement on that of last year, is yet well and substantially made, and will certainly meet the

of the amateur photographer whose means prohibit the purchase of a higher-priced instrument. The camera will easily go into a pocket, which is not always the case with many so-called cameras. Reversible brilliant finder and a good single lens, and the movements include rising and falling front, catch, and focussing scale, rotating diaphragm and ever-set and instantaneous shutter.

Negatives and Masks. Sold by Messrs. J. J. Griffin and Sons, Limited, 20-26, Sardinia Street, Lincoln's Inn Fields, London.
The new border negatives are designed principally for postcard. The designs are very good, and the negatives being on thin glass paper, are unbreakable, and may be printed from either producing with the aid of the masks and discs (enclosed with

(box) results of an artistic character that help rather than detract from the photograph they are enclosing. For those who make their postcards, on either bromide, gaslight, or printing-out cards, negatives and masks will provide a new outlet. They are put up in sets of four negatives and suitable masks, etc., very cheaply.

Printing-out Papers. Made by Helion and Co., 11, Billiter Square, London, E.C.

new P.O.P. possesses many points of novelty that claim attention in addition to the beauty of the results to be obtained. The most noticeable difference between the Helion paper and the majority of those now in use is the absolute mattness of the surface. Yet at

the same time there is a richness given in the darkest shadows that recalls the carbon print without the accompanying gloss. Helion paper tones readily in every ordinarily employed toning-bath, both with gold and platinum salts. The best effects are obtained with the latter, the colours ranging from a rich brown, through sepia to engraving black. Helion stands rougher treatment than most papers. It need not be kept in a calcium tube, like platinum paper. Unlike gelatine paper, it can be washed with hot water, both before the toning and after fixing, without injury to its surface or texture, the time required for the production of a finished and stable print being thus materially reduced.

The picture obtained is, in the first instance, a silver print. The silver, if the treatment recommended by the Helion Company is followed, is (as completely as the reaction will allow it) substituted by platinum. When a properly-toned print is immersed in a solution of mercuric chloride it undergoes no change whatever, while metallic silver would, of course, cause a bleaching of the image. After toning, therefore, the picture is practically a platinum print. While, however, the tone of the ordinary platinotype tends towards grey, that of a platinum-toned Helion paper is, as a rule, inclined towards brown. The platinum bath is a very simple affair. The basis is a 1 per cent. solution of citric or other acid; into this the platinum salt is put. If the solution be strong—say a tube of 15 grains in 20 ounces—toning is exceedingly rapid, and black tints—which, however, must not be allowed to degenerate into greys—are very quickly obtained. The toning is, of course, much more under control with more dilute solutions, and one tube of platinum salts may well be spread out over 200 or 240 ounces of a 1 per cent. citric acid solution. In a large bulk of such diluted liquor hundreds of prints can be simultaneously toned to the same tint. The prints should be examined by transmitted light, and, when deemed finished, be dropped into a basin containing a very dilute solution of washing soda, which, by neutralising the acid of the platinum solution, stops the toning. Uranium, vanadium, iron, or other toning baths can equally well be used, and they result in the production of red, green, or blue prints. While the papers, under ordinary conditions of printing, are particularly suitable for pictures from negatives showing deep contrasts, they may well be used for ordinary or comparatively flat negatives. In printing from such it is well to cover the printing-frame with a layer of yellow tissue paper, or, better, with a sheet of yellow celluloid. The light filter thus employed causes the production of greater contrasts in the print than were present in the negative. The action of the hypo must be allowed to continue in proportion to the thickness of the papers. If not sufficiently fixed dirty yellow blotches will appear on the paper when dry.

THE memorial in Westminster Abbey to commemorate the scientific career of Sir George Gabriel Stokes, the eminent Cambridge mathematician, and former president of the Royal Society, and for many years a member of the Royal Photographic Society, will be formally handed over to the Abbey authorities on Thursday, July 7. It is in the form of a bronze portrait medallion, and has been executed by Mr. Hamo Thornycroft, R.A. As Chancellor of the University of Cambridge, the Duke of Devonshire will make the transfer, and his grace will be supported on the occasion by Sir William Huggins, P.R.S., Lord Kelvin, Lord Rayleigh, and others.

INQUIRIES are frequently made by photographers contemplating a trip abroad as to the difficulties likely to be encountered in passing plates, etc., through the Custom House. As a matter of fact, any real difficulty or annoyance is very rare, and the advice recently given in such a case was, "Don't alarm yourself about the duty question. Declare what you have, and trust to Providence you'll have no difficulty unless you try to smuggle." If, however, the traveller likes to be additionally secure by labelling each packet of plates in the language of the particular seaport or frontier town he will have to pass through, printed tickets in the various European languages may be obtained at most of the photographic dealers. In the case of America, it is often a serious consideration whether it is not best to purchase both camera and materials after arrival in that country, unless an American-made instrument be carried, as the duty payable on taking a European-made camera into the United States is 45 per cent. ad valorem, and 25 per cent. for plates, etc.

A METHOD OF SUITING SCREENS FOR THE PHOTOMICROGRAPHY OF STAINED BACTERIA.

DR. SPITTA read an interesting paper bearing this title before the Quekett Microscopical Club, on June 17. He commenced by saying that as photography had become the handmaid to microscopy, anything which assisted the photographer in the better and more truthful rendering of microscopical objects really benefited the microscopist. It was on this ground that he ventured to occupy the attention of the club with the subject in question. He added that he wished it to be distinctly understood that he did not bring before them the use of screens for increasing contrast between coloured objects as anything new, but as the method for ascertaining scientifically the correct antithetical dye to use, by employing the spectroscope in conjunction with the photographic plate might not be familiar to some of the photomicrographers present, he deemed the subject worthy of a few minutes' attention. Screens were used in photography for two purposes—to improve definition and to increase contrast. He should deal with the latter only. To make what followed better understood, Dr. Spitta carefully called attention to the difference between the human eye and the photographic plate in their methods of perceiving contrast in coloured objects. The eye recognised the difference by contrasting the coloured objects themselves, whereas the photographic emulsion merely recognised differences in intensity of the light from each. For example, red light was merely the name given to the physiological recognition of about 460 millions of millions of taps on the retina in a second of time; whereas if the number of such vibratory shocks increased to about 678 millions of millions, we called the light violet; the photographic plate, however, "cared not for these things," and only showed contrast as an indication of different exhibitions of light intensity; at least, that is what it practically amounted to. Hence, if the photographer wanted to increase contrast when photographing stained bacteria—say a blue bacillus on a white ground—he must reduce the intensity of the blue to make it become as dark as possible. Dr. Spitta then proceeded to show how this could be done by using a certain yellow screen, which turned the blue bacillus into a black, the field becoming of the same yellow as the screen. If now a photographic plate was chosen which was sensitive to the same kind of yellow as the screen, a photograph could easily be taken. Illustrations were given by means of the lantern. Dr. Spitta next showed how necessary it was, after what he had just said, to know the sensitive properties of most kinds of orthochromatic plates on the market, the peculiarities of each being designated by him as its "eye." A lantern slide was here thrown on the screen, showing the audience the "eye" of most of the orthochromatic plates to be procured, using both short and long exposures. It was very instructive, for it showed at what wave-length the sensitiveness commenced and finished for all varieties of emulsion. Step by step the audience were taken through the subject, and shown in detail how they might study these peculiarities for themselves. Dr. Spitta also exhibited and briefly described the form of spectroscope which he had employed in his researches. It was made by Zeiss, and its special feature lay in the projection of the wave-lengths, by means of a scale, of all the different colours in the spectrum, upon the plate at the same time as the spectrum was being photographed. This was a great convenience, and placed the method of comparison upon a scientific basis, for it had often been pointed out how useless remarks were when employed by a lecturer who spoke of effects "somewhere in the blue" or "near the end of the yellow," instead of in terms of the wave-length of the colour at the situation to which reference was made. Real spectra were now thrown on the screen by means of a second lantern fitted with a large bisulphide prism. These, while adding largely to the interest of the subject, also gave the lecturer an opportunity of explaining various details, such as the use of screens, the meaning of absorption bands, and how the eye perceived these effects differently to the photographic plate. Dr. Spitta went on to explain that in dealing with bacteria, the photographer had mostly to deal with three dyes or stains—viz., Löffler's blue, gentian violet, and carbol fuchsin. Lantern slides showing the method of selecting suitable screens for each of these stains were thrown on the screen, and the details carefully gone into, and finally

photographs of anthrax bacilli magnified 1,000 diameters, stained with each of the three dyes, were in succession exhibited, illustrating the effect of photography with and without the contrasting screen. It was unanimously admitted that the improvement in detail and definition was most marked.

FORTHCOMING EXHIBITIONS.

June-October.—Glasgow Photographic Exhibition. Secretary, Glasgow Gallery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Secretary, W. Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee Hall, Andover.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.

September 16 to November 5.—Photographic Salon, Dudley Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Fifth Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. Secretary, Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Secretary, W. N. Beal, 155, Thorold Road, Ilford.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Secretary, James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-16.—Ipswich Camera Club. Hon. Secretary, R. Sutton, 37, Henley Road, Ipswich.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Secretary, G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102 West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, J. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. Issott, 62, Compton Road, Harehills, Leeds.

News and Notes.

SE Exhibition at the R. P. S.—Our readers are reminded that the show of studies in gum bichromate by Robert Demachy now on view at the Royal Photographic Society's House, 66, Russell Street, remains open until Saturday, July 9.

THAMPTON Camera Club.—On the 27th inst. the members of the club held a print competition, the subject being "Cloud Study." The premier position was awarded by the judges to Mr. C. D. Kay, who wins the bronze medal given by the club.

A new series of animated pictures now being presented by the Bioscope at the Alhambra Theatre are well worth seeing. The edition to striking pictures of the war in the Far East, the Motor Cycle, etc., a very popular and realistic series showing the making of a newspaper is given. The pictures show every phase of the process from the noting of the incident to the publishing of the journal to the public. They are extremely well done.

Mrs. JULIA MARGARET CAMERON, whose exquisite photographs of years ago are now being exhibited at the Serendipity Gallery, 10, St. John's Church, St. John's Grove, has yet another title to fame in those days. She was noted for a succession of superbly beautiful housemaids. Her young women had other duties than those of ordinary domestic help. For the dimly mysterious Tennysonian heroines which her photographs produced are housemaids. To-day housemaids will be more "sh" than ever.

D. PACINI has sent from Rome an account of careful experiments made by him with the object of observing the effects of light described by M. Blondlot and other investigators. Though his observations were made under very favourable conditions, he was unable to detect any increase of luminosity of a phosphorescent substance caused by unknown rays from strained or tempered steel, an arc lamp, a Nernst lamp, sound vibrations, or a magnetic field. Various French observers have affirmed that in each of these cases X-rays are emitted which produce an effect upon the screen.

The Prime Minister has consented to receive a deputation from the British Association for the Advancement of Science at the House of Commons on Friday, July 15, at 3.15 p.m., with the object of discussing the views of educationalists and others, who advocate the granting of an increased endowment of universities and colleges on the part of the State in the interests of higher education and of national progress. Sir Norman Lockyer, president of the association, will introduce the deputation, which will comprise academic, municipal, labour, and general representatives.

ROYAL Photographic Society.—On Tuesday evening (June 28) the meeting of the session was held. Messrs. C. E. K. Mees and Sheppard gave an interesting, and what is likely to prove an important, paper on "Instruments for Sensitometric Investigations. A Historical résumé," their researches showing that they had carried out the sensitometric investigations of Harter and Driffield to a greater degree of accuracy. The paper dealt exhaustively with a new machine for accurately coating plates in small quantities, with the instruments, an enclosed instrument for the Hurter wheel, a standard acetylene light, a developing thermostat for the control of temperature during development, photometers—the Hufner photometer, and some new fittings for the measurement of light. A full report of the lecture will be published in these pages later.

PHOTOGRAPHS with the Two-Foot Reflector of the Yerkes Observatory.—Seven very fine specimens of the work done with the two-foot reflector of the Yerkes Observatory are published in Vol. VIII. of the Annual Publications of the University of Chicago. These are of the giant nebulae of Orion and Andromeda; of the spiral nebulae of the 33 Trianguli and Messier 51 Canum Venaticorum; of the carded-like nebulae in the Pleiades; and of the torch-like nebulae in the constellation known as N.G.C. 6960, and N.G.C. 6992. These two last form part of the same extended nebula, but they present some striking differences in their relationship to the stars. In the first case the

nebula seems to act as a wall or barrier separating a region strewn very thickly with stars, from a sparser field; in the other case no such difference in the number of the stars seems to exist on the two sides of the nebula, which itself appears to lie in a district of few and small stars.

MR. FREDERICK SANDYS is dead. The announcement will have a pathetic interest for all those who have watched an artistic career in which the merits have outstripped the resulting rewards. Of his seventy-two years the most successful were perhaps those that saw him at his black-and-white work on the "Cornhill" and "Once-a-Week." His pictorial skit on the Pre-Raphaelite Movement won for him at once the candid admiration and the friendship of Rossetti. For several months he lived under Rossetti's roof; but the quarrel, perhaps inevitable when the temperaments of the two men is taken into account, came in 1869, and arose out of Rossetti's belief that Sandys adopted subjects for pictures which Rossetti had already sketched out or discussed. As an illustrator in black and white he has, however, established his fame; and in no drawings was he more happy than in those which illustrate some of the pages of Mr. George Meredith's "Shaving of Shagpat." Mr. Sandys was a good talker; he told his stories drily and well; and, of course, his intimacy with Rossetti and other literary celebrities gave him a never-failing interest of theme.

THE National Trust for Places of Historic Interest and Natural Beauty has acquired another beautiful view-point on the Kentish Hills. Two miles from Westerham, and about three miles from Edenbridge, the land, extending to about three acres, crowns one of the southern ridges of Crockham Hill, and is approached on one side by paths cut through the copse wood on a steep bank full of primroses and wild hyacinths, and on the other by a track following the edge of the intervening fields from Westerham Common. The view on a clear day, as one sits on one of the rough timber seats the Trust has erected, is a beautiful and extensive one, embracing most of the Weald of Kent and Ashdown Forest to Leith Hill, Blackdown, and the hills of distant Haslemere. The enjoyment of this beautiful halting-place is owed to the generous donor, who by leaving a sum in money "In Memoriam" with Miss Octavia Hill to be used at her discretion has enabled her to purchase and present the land to the National Trust as a lasting memorial to the benefactress herself, and a means of healthful and quiet enjoyment to all who, loving the beauties of an English landscape, care to visit the spot. This should prove an ideal place for a photographic society's outing.

BIRMINGHAM Photographic Society.—A Garden Party will be held on Saturday, July 2, to which every member is invited, in the grounds of their residence, at Barnt Green, by the President and Mrs. A. J. Leeson. For the entertainment of members there will be tennis and croquet, also unique photographic competitions. Groups of living models will be specially provided for the occasion as follows:—Group No. 1: "Dairymaid and Cow." Group No. 2: Four models dressed in Old English Costume." Group No. 3: "A Country Type." A silver medal will be awarded for the best set of three prints, consisting of one print of each subject. A bronze medal will be awarded for the best single print submitted of either subject. A certificate of honour mention will be awarded for the best print from a cloud negative taken during the afternoon. Three cameras will be provided inclusive of the club cameras, being one camera for each group. A suitable supply of plates will be on hand. The medals and certificate are the gift of the President. The medals will be struck from the new design obtained by competition at the Birmingham School of Art, and not previously issued. Mr. Harold Baker will act as judge. We can commend this original idea of the energetic "Brum" Society to photographic societies all over the Kingdom.

SUN Fête on the Eiffel Tower.—M. Eiffel's famous Tower on the Champ de Mars has of late fallen somewhat out of favour with the Parisians, but last week it regained for a few hours its old popularity. June 22nd was the first day of the summer solstice, and a party of Paris astronomers, mathematicians, and men and women of learning had resolved to celebrate the advent of summer by holding a festival in honour of the sun. Among those present were Prince Roland Bonaparte, MM. Eiffel, Poincaré, Flammarion, and many other distinguished scientific people. After they had

dined at the restaurant on the first floor, M. Flammarion delivered a lecture on the sun, illustrated by solar photographs. Afterwards there was a concert, with songs and recitations appropriate to the occasion. At half-past one a group of enthusiasts went to the top platform and waited to see the sun rise. M. Flammarion has thought fit to state, in connection with the ceremony, that it is absurd to accuse him and his associates of being pagans, and of endeavouring to revive sun worship. Every religion, he said, honoured the sun. Their intention had simply been to revive a pretty cult, which was as old as the world, and which they hoped in the future to celebrate annually. The average photographer is probably more of a sun worshipper than M. Flammarion and his friends.

THE Biograph at the Palace Theatre includes some very fine films indeed of topical interest. Of course, the Gordon-Bennett race and the incidents of the Russo-Japanese War come in for a full share of attention, and the pleasing brown colour of some of these latter is a very welcome relief to the usual hard black and white tones we are accustomed to. The pictures showing the Czar have almost a pathetic interest. We see the "mighty white Czar of All the Russias;" we can look into his face and gaze closely into his eyes. The pictures are so good that one can almost follow the train of thought that prompts his various motions. First one sees this little, tired man at the blessing of officers departing for the war. Priests in gorgeous vestments perform the rites with graceful movements, and the long-limbed officers come striding up easily and carelessly. But the little Czar shifts from one leg to the other, glances at the toes of his boots, attends anxiously to the set of his sword as though he had never hung one at his side before, or hurriedly smoothes his moustaches. He drinks the health of a departing regiment, and he shifts from leg to leg as he stands beside the table on which is set out the wine. Again he glances apprehensively over his shoulder, again he sees to the set of his sword, again he smoothes his moustache. He takes the glass of wine, raises it, and looks into it gravely as though death might lurk there. Then, with a sudden movement, he straightens up and drains it to the dregs. A moment later he is again shuffling aimlessly round the table. Then he vanishes, and he has not smiled once. The audience has watched quietly; there has not been a suspicion of applause. From the grand strains of the Russian national hymn the orchestra changes its notes into a jingling air. The light of the biograph shines out again, and the gallery cheers as Japanese sailors at leap drill on the screen.

In the county of Devon, which for its size, area, and great attractions has singularly few aggressively active photographic societies, since the fine summer came in there has been plenty of good weather for outdoor photography. The summer sessions are now arranged and the Plymouth Photographic Society has started with a most excellent beginning. A large party on Saturday last accepted the invitation of Mr. Frederick Johnson (President) and Mrs. Johnson, and journeyed to Ivybridge. This spot is very well known indeed to the inhabitants of the big towns within a dozen miles of it, but it is by no means as well known to the visiting photographic picture maker as it deserves to be. The party that journeyed with Mr. Johnson on Saturday were not all photographers, as the invitation included friends of the members within its scope, and this judicious intermingling made the jaunt a very pleasant one. The vicinity of Ivybridge, toward the moor, is very elevated country, and thither the party, under the guidance of Mr. Chalwell, head gardener to Mr. James J. MacAndrew, wended its way. The route lay in the magnificent Stowford Woods, rich in all the native varieties of trees, all in their glorious and tender leafage, through which the sunlight glistened and flickered, giving the soft, cool light of a cathedral aisle. It was a glorious day, and all around the birds were carolling in full song. Deep down in the valley ran the River Erme, tumbling with many falls over the granite boulders in its course, the soft murmur of its voice reaching the party, now faintly and now more strong, as the gentle breeze came through the wood. Upward continuously the course was pursued, until the mansion and grounds of Lukesland were reached. This was a veritable floral fairyland, in which rhododendrons, benthamias, and calmasias formed great masses of blossoms. There was profusion of flowers of all the usual kinds found in such places, with many old-fashioned varieties which are far too little seen nowadays. Great masses of bamboo luxuriantly flourished, and

it was difficult to realise that where the party was gathered 900 ft. above sea level. The grounds are famous for the splendid collection of conifers, many rarities of the pine family rearing their crests to the sky. With such brilliance and variety there was much photography done, though the time was all too short. Then the party wended its way down to the ancient village of Ivybridge, to the hostelry, the London Hotel, jutting on a bridge that touches the parishes, where the President had invited the party to join him. Mrs. Johnson at a strawberry tea, with an abundance of the clotted cream for which the district is famous. At the close of the function, Mr. J. J. Johnson, Vice-President, proposed in felicitous phrases a vote of thanks to the President, which was seconded by Mr. Chas. R. Rowe, supported by Mr. H. S. Hill, and very heartily carried. Mr. F. Johnson, in replying, spoke of the pleasure the hotel had afforded him, greatly enhanced by the company of those who had accepted his invitation, and spoke of the very hearty way in which the members had supported him on every occasion he desired their co-operation, and especially at the time of the very successful exhibition. He begged to be allowed to include Mr. Grist in the vote, as the Hon. Secretary had taken considerable pains to make both the events referred to the success that was apparent. After a few words from Mr. Grist, the party made its way to the station in the cool and charm of a delightful summer evening, fitting termination to a very enjoyable outing.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July	Name of Society.	Subject.
1.	South London Photo. Society.	<i>Luna Paper.</i> Demonstrated. L. Allegre & Co.
5.	Nelson Photographic Soc'y	<i>Trimming, Mounting, and Framing.</i> Mr. F. Whitaker.
5.	Rotherham Photo. Society	<i>Carbon Process.</i> Mr. W. Firth.
7.	Hull Photographic Society	<i>General Meeting.</i>
8.	Watford Photographic Society	<i>Informal Meeting.</i>

FORTHCOMING COMPETITIONS.

June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News" 9, Cecil Court, Charing Cross Road, London, W.C.

June 30.—Kodak. £1,000 in cash prizes for pictures taken with Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging two pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manag. Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £200 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

THE PHOTOGRAPHIC PROFESSION AND THE "B.J." JUBILEE.

To the Editors.

Gentlemen,—I have been desired by the Committee to offer you our congratulations upon the BRITISH JOURNAL OF PHOTOGRAPHY having passed its fiftieth birthday, and to express the hope that it long continue its career of usefulness under your able guidance. Representing professional photographers generally, we have to thank you in their name for the generous way in which you have shed over the interests of the profession, and we consider that the least of the benefits the JOURNAL has conferred upon our community is the institution of this Association, and for your own personal efforts in the matter we cannot be sufficiently grateful.—Yours very truly,

ALFRED ELLIS, President.

The Professional Photographers' Association,
51, Baker Street, London, W.
June 24, 1904.

A METEOROLOGICAL DISCOVERY.

To the Editors.

Gentlemen,—I have noticed, with some interest, an article under above heading in the "B.J.P." of June 24. I think this excessive continual rain affects the photographer more than anyone else; before, it is only natural that he would do his best to discover the cause of such an "evil," as the article puts it. I really do not think ought to blame Signor Marconi for the cause of such unusual nature. We have not the slightest proof that his wonderful discoveries of wireless telegraphy is the cause of such inclement weather. People of Fraserburgh and Poldhu have our sympathy for the loss and inconvenience brought about by such weather. So have the people of other places, where there is no wireless telegraphic station. I do doubt that Signor Marconi would be only too pleased to remove the dreaded instruments to Egypt or elsewhere, where rain is wanted. Such instruments cause rain?—Yours truly,

C. H. B.

HISTORICAL.

To the Editors.

Gentlemen,—Allow me to thank Mr. G. T. Harris for his very delicate compliment in the letter on page 580 of your last issue. I am glad, however, that he will be disappointed, because I had no intention of giving aught but "a few idle thoughts from an idle hour," and mainly not anything like a series of articles; but I hope within the next few months to prove by results many of the statements made in the last two issues.

Mr. Harris is quite correct as to the first use of ammonium picrate, Albert of Munich placed his collodion emulsion on the market in 1833, and this contained ammonium picrate. In "Eder's Jahrbuch," 1833, II. Theil, page 406, occurs the following passage: "Dr. Albert recommends the picrate salts as light filter for orthochromatic work. He incorporates the same in the sensitive film itself, as he adds to the collodion emulsion a solution of silver eoside in ammonia, in which free ammonia is neutralised by picric acid; by this means also the eosine, which acts prejudicially on the pyroxyline, is removed, and the silver eoside being destroyed."

In page 402 of the same book Dr. Eder states that Dr. Albert, in the summer of 1833, at the famous Vienna School, made exposures with his collodion emulsion, and gave the same exposures as for sensitized gelatin-bromide plates, a hitherto unattained result. The use of ammonium picrate was also recommended by Dr. Jonas, in his paper, Corresp., 1891, p. 318, and Major-General Waterhouse transmitted this paper, but I cannot trace an independent suggestion by him as to this use of the picrate.

I had not in my mind, when writing, collodion emulsion at all, or I should have certainly given Dr. Albert the credit. M. Vidal, I still think, was the first to suggest its use for gelatine plates in the "Moniteur de la Photographie," 1891, p. 183, and it was then recommended by Burton.—Yours faithfully,

E. J. WALL.

Foots Cray, June 27, 1904.

COPYRIGHT IN INDIA.

To the Editors.

Gentlemen,—In your issue of May 6 I notice an inquiry in your column "Answers to Correspondents" from H. C. S., Bombay, with reference to copyright in India.

About four years ago, whilst carrying on business in India, I endeavoured to protect certain photographs of mine from being pirated, and applied to the Patent Office, Calcutta, to have them registered, and received a reply direct from the Government of India, through the official head of that department, to the effect that there was no copyright for photographs in India. A drawing of an article, designs, etc., can be registered at the Patent Office, but this gives protection over the particular article only.—Yours truly,

F. SKEN.

Colombo, Ceylon,

May 30, 1904.

A PHOTOGRAPHIC Sea Trip.—Nowadays we go to Deal and Dover from London almost as quickly and far more comfortably than an older generation of trippers went to Greenwich or Gravesend, and this is exemplified this week, when the Koh-i-noor, of the New Palace Steamers line, makes the first of a series of excursions to Dover and back by daylight. From now until the season's end this excellent steamer is to start four days a week from Tilbury.

NEXT year the meeting of the British Association for the Advancement of Science is to be held in South Africa, and Professor George Darwin, F.R.S., has been elected President. No fitter choice could have been made. The son of the great naturalist is an astronomer and a mathematical physicist of the first order, somewhat unlike his father, who used to say that he could never understand an equation, but otherwise like him in wide scientific sympathies and cautious reasoning. No part of the world has more to expect from science than the Transvaal, Natal, Orangia, and Cape Colony.

ON Saturday, the London and Provincial Photographic Association had an enjoyable outing to St. Paul's Cray Common, the land of birch and bracken. Unfortunately, the sky was dull, so only those who had brought tripods with them could make exposures with any certainty, and the expedition therefore resolved itself into a prospecting tour for future visits. The celebrated caves near the station were visited, and were found very interesting. Supper was taken at the Bickley Hotel, Mr. Oscar Hardee, photographer, Chislehurst, presiding. An elaborate list of the usual toasts prepared by the recorder was unanimously voted as not wanted, but Mr. Drago briefly thanked the chairman for his presence and welcome to the locality. During the evening the hon. secretary, Mr. Grant, Mr. Hardee, and Mr. Furley Lewis favoured the company with music, vocal and instrumental.

SCIENTISTS do not expect popular fame, but our greatest scientist, Lord Kelvin, who attained the age of eighty on Sunday last, has added so much to our knowledge and has achieved so much in scientific inventions that he deserves to be honoured by the "man in the street" as well as by his fellow labourers in science and physics who can estimate his remarkable work. Yet he said not long ago that despite fifty years of experimental investigation he could not help feeling that he really knew no more than he knew fifty years before. Walking through a great electrical works, he said to a workman quite casually, "What is this electricity of which I hear so much?" The man, not recognising his questioner, answered, "I am sure I don't know, sir." "More do I," replied Lord Kelvin. And that expresses his humility in discussing a subject on which he knows probably as much as any living man. It is this Newton-like humility which has endeared him to his colleagues, for he has always been ready to hail with enthusiasm any of their discoveries and to anticipate far greater revelations of what he believes are the evidences of a divine force aiding humanity in its life and work.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

W. H. Chillman, 207, St. Albans Road, Watford, Herts. Photograph of an Advertisement Placard.

H. D. Buttrum, 18, High Street, Stony Stratford, Bucks. Photograph of the Queen's Oak, Pottersbury Lodge, Northampton.

T. R. Hammond, 1, Rose Hill Street, Conway, Carnarvonshire. Photograph of Conway Castle and Suspension Bridge, Showing New Footway.

T. Dann, 83A, Brighton Road, Redhill, Surrey. Photograph of Col. W. F. Cody, "Buffalo Bill." Photograph of Col. Cody and Two Indian Chiefs.

W. J. Reed, 2, Marina Arcade, Bexhill-on-Sea. Two Photographs of Group of St. Peter's Clergy, Bexhill.

I. C. Thomas, 6, Belvoir Street, Leicester. Photograph of Baby "Thomas" in Bath.

FIVE PER CENT. SOLUTION.—"MOORE" says: "Kindly let me know how to make up a 5 per cent. solution—how much of the solid and how much liquid is required." In reply: Dissolve five parts of the solid in, say, ninety parts of water, and then make the bulk up to a hundred. This is what is generally understood as a 5 per cent. solution.

LENS QUERY.—"K. L." (Allahabad) asks: "(1) Kindly give me full particulars of removing spots of lens. (2) Also, let me know the price of the postal guide of London." In reply: (1) We must trouble you to make this query a little more definite. We do not understand what you mean by "spots of lens." (2) The price of the "Postal Guide" is 6d.

ALBUMEN PROCESS.—"G. P." says: "I want to make a few lantern slides by the albumen process. Can I expose in the camera whilst wet, same as collodions, or must they be used dry?" In reply: The plates should be exposed dry. The exposure will be very long in the camera. Unless the pictures are to be reduced we should recommend you to print by contact.

CLOUDS IN COLLOTYPE.—THOMPSON AND LEE write: "Could you kindly tell us the usual method adopted by large colotype firms in putting clouds in the views of their pictorial postcards? We shall feel obliged with any information on this point which you can give us." In reply: The usual way is to put the clouds in the negative. If the skies are dense they should be reduced a bit.

BOOKS WANTED.—"RETOUCHER" asks: "(1) Can you recommend a good book, or books, on retouching? I want one that goes into the work thoroughly. (2) Also, are there any books with lighting and posing studio work?" In reply: (1) "The Art of Retouching Negatives and Finishing and Colouring Photographs," by Rob. Johnson; or "Practical Retouching," by Drinkwater Butt. (2) "The Studio and What to Do In It," by H. P. Robinson, and "Artistic Lighting," by Jas. Inglis. The books may be had through any of the dealers.

VARIOUS QUERIES.—"PUZZLE" asks: "Will you please answer the following?—(1) In toning P.O.P. prints I alum the prints after fixing. Could I add alum to the 'hypo' bath to save the time needed otherwise without affecting the permanence of prints? I find that when hypo and alum are mixed in solution it turns 'milky,' and gives off an unpleasant odour. Is this of any consequence to prints? (2) In a recent issue of the BRITISH JOURNAL OF PHOTOGRAPHY there was an article on 'A Useful Print Meter' (which I have mislaid). Could you give me the name and price of the meter mentioned? (3) Could you tell me of a good (but inexpensive) book on lenses which would help me in purchasing, and also give me a slight knowledge of

uses of different lenses?" In reply: (1) Your present method of working is far preferable to adding alum to the fixing bath if permanency is a consideration. (2) We do not think that a meter is on the market (p. 313). (3) "A Simple Guide to Choice of a Photographic Lens," by T. R. Dallmeyer; "Photographic Lenses," by Conrad Beck.

LENS QUERIES.—"S. E. T." says: "I shall be very much indebted if you will give me advice on the following:—(1) Do you consider a studio 24 ft. by 10 ft. large enough to do the best work in? Do you think it rather short for full-length pictures? (2) The light used would come entirely from the north, there is a building opposite the side light, at a distance of about 15 ft., and is not quite as high as my building. Would this materially interfere with the strength of the side light? (3) Having the focus of the lens, how can I ascertain the distance between the sitter and the camera for a full-length portrait? (4) Considering the length of the studio (24 ft.), what length of focus lens could be used to get perfect definition and no sign of distortion?" In reply: (1) The studio is not too small to do good work in, though it would be more convenient if it were a little larger. (2) It would to an extent, though not very materially. (3) With a lens of 12 in. focus a distance of about 18 ft. is required between the camera and the sitter for a full-length cabinet picture. (4) One of about 12 in. focus for cabinet size.

SALE OF PRINTS.—A. WALKER writes thus: "Having been asked what I would take a whole-plate negative of troupe for said 7s. 6d., but not being able to get more than 5s. I agreed (but at the same time I did not think much of it), so I took two negatives and supplied one for 5s., but while I was they asked me to take two half-plates different positions, which I did; no price agreed for these at the time, but when I saw proofs of same I was asked how much for the two. I said As I could not get more than 5s. the two I thought it better to take that, as I had done the work, but before parting with the negatives I printed five of each, making fifteen prints, and thought I could sell one or two finished prints to some of the troupe, which I did; but what I sold was done openly, and was given to understand the negatives were wanted to make some prints to put in shops and hotels as an advertisement. Nothing was said to me about the troupe wanting to take prints, which it looks like to me, as I have enclosed a copy of what was sent to me to-day on the matter from the head of the troupe. Thanking you for your advice on this, I may say I only supplied three 1-1 plates and four half-plates at each, only being five in the troupe. I am sorry I had anything to do with such people. Also, will you advise me if I could make use of the second whole-plate I have in my possession? I choose to? I may say that there was nothing signed between us. I only sent bill for three negatives, 10s., and the prints were finished before I received the money for plates. In reply: You are certainly in the wrong. You have no right to make use of the prints without the consent of the sitters. You were paid for your work—whether much or little is of no matter. You have no right to use the negatives you have. We should advise you to make the best terms you can with the aggrieved parties. Kindly write on one side of the paper only in future, please.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.
ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION. Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

THE BRITISH JOURNAL JUBILEE NUMBER.

Special Jubilee Number of THE BRITISH JOURNAL OF PHOTOGRAPHY, which we published on Friday, June 10, met, we are pleased to say, with a most cordial and durable reception at the hands of the photographic public—indeed, the success achieved was so striking and instantaneous as to cause even ourselves, who had anticipated the Special Number would secure a wide degree of appreciation, the liveliest feelings of gratification and assurance at the chorus of commendatory approval meted to the issue.

Several extra thousands of the Special Jubilee Number have been printed, and they are selling rapidly at the ordinary price of twopence per copy, or by post twopence-penny. The number consists of a total of 132 pages, and forms the largest ordinary issue of any photographic journal ever published in the United Kingdom. The contents include thirty special articles by the foremost photographic authorities of the time; a history of THE BRITISH JOURNAL OF PHOTOGRAPHY since its foundation; and about 100 original portraits of celebrities connected with photography; thus forming a unique and most interesting souvenir of the Jubilee of the oldest photographic journal in the world.

As this souvenir number of the JOURNAL is in such demand, and is shortly likely to be scarce, readers at home and abroad who have not yet secured a copy are advised to do so without delay.

EX CATHEDRA.

Light and Chemical Action on Platinum.

Platinum is almost a typical substance of those unacted on by ordinary chemical agents, yet M. Berthelot has recently made an interesting communication to the Paris Academy of Sciences, showing how, under the action of light, the immunity is destroyed. He finds that pure platinum under the influence of strong hydrochloric acid is slowly attacked. The presence of manganous chloride increases the effect, the more as the proportion of manganese present increases. Light, M. Berthelot says, apparently acts in the same manner as atmospheric air when the latter is used as oxidiser for organic compounds: it seems to cause the fixation of free oxygen, which replaces the chlorine of the hydrochloric acid. Gold also, when treated similarly, is found soluble in hydrochloric acid. These facts, however, do not at all militate against the stability of platinotype prints which, so far as the image is concerned, still retain their reputation of absolute permanency as regards the action of time and atmospheric agents.

* * *

New Process for Welding Aluminium.

We have often referred to the difficulties attending the joining together of aluminium surfaces as required, for example, in making the tubes and fittings for lens mounting, etc; and recently a description has been published of the Cowper-Coles welding process, which is stated to be especially suitable for wire rods and tubes and other rolled or drawn sections. The process involves the use of a special machine for clamping together the parts to be welded. The best used is that from an ordinary benzine lamp, and as soon as the parts have arrived at the necessary temperature slight pressure is applied by the machine, which causes the joined surfaces to unite, a ring of metal being squeezed out. This ring consists largely of aluminium oxide, and acts as a supporting and insulating collar, the molten metal being retained within this collar. The great feature of the process then comes into play; the junction is instantaneously quenched by a douch or jet of cold water applied from a special jet attached to the apparatus; at the same instant the handle that turns on the jet interposes a screen between jet and flame.

* * *

Photographs for St. Louis.

Of the photographic section at the St. Louis Exhibition we have heard much, but there are a number of other photographs in connection with the British exhibits at the Big Fair which hitherto have not attracted attention. They serve to show incidentally how dependent our arts and manufactures are upon photography for

picturing processes and results. It is now the common custom for engineers in charge of big works to record by photography daily or weekly progress, and many such pictures, notably those taken in connection with the great Assuan dam across the Nile, have gone to the St. Louis Exhibition. The War Office have sent plans and photographs showing the most recent types of military barracks and hospitals. The Mining Department of the Home Office have sent a number of photographs to help in their large collective exhibit relating to British mining during the past thirty years. The Board of Education (Geological Survey and Museum) have contributed a collection of metallurgical photographs. One exhibit in this department is of extreme interest. What is known as Frosterley marble, which was used in the adornment of several of our British churches and cathedrals for a period covered by half a dozen centuries, had been lost. But its vein has recently been re-discovered, and several specimens, both rough and polished, have been sent for exhibition, together with photographs of the same stone as found in our ancient buildings. We could not very well send samples of our cathedrals across the Atlantic, however much Brother Jonathan would like us to do so. But we send the next best thing possible—photographs of them.

* * *

Trichromatic Illustrations.

A glance into the windows of any of the leading booksellers' shops reveals the fact that coloured pictures, as illustrations to volumes on all kinds of subjects, are very much in evidence, and that such pictures, as well as those used for illustrative purposes which are in monochrome, are either photographs or reproduced by photographic process. Photography is, indeed, becoming every day more necessary to the producer of books, as it is to the publisher of periodicals. As a case in point we may mention Prof. Hall Griffin's "Life of Browning," which will presently be produced by Messrs. Methuen. According to the "Athenæum," "Prof. Griffin has photographed every accessible spot, character, and picture mentioned in Browning's works, including every yard of his walk from the stall in the Piazza San Lorenzo, Florence, where he bought his old yellow copy of 'The Ring and the Book,' to his lodgings." Turning to pictures of another kind altogether, which presumably owe their existence to photographic process, we learn from the "Times" correspondent at Cracow that the Russians are distributing hundreds of thousands of coloured pictures in Moscow and in the rural districts of Central Russia, with the encouragement of the censor. These are pictures relating to the war, and in all of them the Russians are represented as the victors, and the poor, feeble Japanese as utterly crushed. Japanese ships are shown sinking, their towns shattered to pieces by Russian guns, and the Japanese infantry being run down like rabbits. In one picture of the battle of the Yalu the Russians are seen driving the Japs in confusion across the river. There will be stirring times in these districts of Central Russia when the people learn the truth.

* * *

Formaline in the Atmosphere.

Formaline, or solution of formic aldehyde, as it would be termed by the chemist, offers a conspicuous example of photographic conservatism. It is now several years since, on the strength of a report of a foreign philosophical society, where it had been recommended for hardening gelatine for microscopic slides, we suggested a probable sphere of usefulness for it in photographic techniques. Some time afterwards it was put on the market for photographic use. It is now obtainable at any dealers in photographic chemicals; yet we have had the entrée of scores of dark-rooms where not a trace of it was to be

found. For the prevention of frilling, or the hardening of a film to be rapidly dried, it is invaluable. It has been suggested that its use might lead to the deposition in the film of silver compounds from the hypo fixing solution, if it were not well washed out, and possibly it may account for the otherwise unaccountable neglect that has been shown it; but whether there is any ground for such objection can be shown in a moment. Let anyone take a small quantity of used hypo solution in which many plates have been fixed, and add to it even half its bulk of commercial formaline. It will be found, at the end of half an hour, that the liquid is perfectly limpid, clear, showing that no precipitation has taken place, nor, *a priori*, would be likely to take place, in the film. The theory is a figment. At a recent meeting of the Paris Academy of Sciences, M. H. Henriot made an interesting communication, regarding formaldehyde in the air. He found it present in measurable quantity; indeed, to a great extent as a thousand times as much as the ozone present. Most people are familiar with the effects attributed to the presence of ozone in the air, even in small proportion in which it is found; and, granted the correctness of the usual estimations of ozone, it would be reasonable to suppose but that the presence of formaline in a thousandfold proportion must have some action. Whether it has any effects on the film or on a plate is a question worthy of study; we are all familiar with the defects liable to be shown by an over-long exposure. How much may be attributed to this formaldehyde? That this estimate of the amount of formaline is not a fanciful one only, is shown by the fact that M. Henriot proved his results by making control experiments with air contaminated by a known amount of the aldehyde, his results in each case being in exact accordance with one another.

* * *

Iodine and Hypo.

The method of testing prints for the presence of hypo by iodine is too well known to need description; but a further use for iodine in photographic operations is the less usual one of making a solution of a definite strength for testing the purity of a given sample of hypo—in other words, ascertaining the percentage of the actual salt present in a sample of reputed hypo crystals. This is a proceeding most advisable to take when obtaining a fresh supply, say, a fresh cask, of this essential chemical; and it is not the mere satisfying of a pedantic desire for purity that renders this testing desirable. The presence of sulphur has been held to be inimical to the permanency of prints fixed in hypo contaminated with it; and, further, the addition of sulphate to hypo crystals enables the salt to be sold at a lower price, and the adulteration might easily pass undetected. The sophisticating salt, however, possesses one characteristic that leads to its detection if present in large quantity as we know from our own experience is sometimes the case. Sulphate of soda loses its water of crystallisation after being exposed to ordinary atmospheric air for a little time and effloresces to a conspicuous degree. We have seen a hundredweight cask of hypo adulterated with so much sulphate as actually to give it the appearance of having been dredged with flour. This is, of course, an extreme case; but the sophisticated salt is frequently present in quantity sufficient to give an artificial dryness to the hypo, which, though it cannot be called actually a deliquescent salt, will yet tend to cake together when exposed to air, and then become the reverse of "dry" looking. The best method of obtaining pure iodine for this purpose has recently been published by Herr L. de Ronwick, and may with advantage be here placed on record. After reviewing

various methods of obtaining pure iodine for titrating po, etc., he recommends the actimon by the dry way of chromate of potassium on iodide of potassium, feeling assured that the impurities usually present in these two are generally without influence in the final result. Further, it is very easy to purify these salts if thought desirable. A very intimate mixture of one part of iodide with three-fourths of bichromate is heated, and the iodine driven off condensed in a taxed glass bulb, which, upon being weighed with the contained iodine, enables a solution of exact strength to be rapidly and directly made.

* * *

Magnesium and Aluminium The use of these metals in powder for flash-light photography is now of such common occurrence that it might be supposed that there is nothing to learn about them, yet, as our "Answers to Correspondents" column shows, considerable ignorance as to the modes of procedure still prevails. There is one point about their employment which we would emphasise in the strongest manner, and that is the danger of making up what may be termed the pyrotechnic mixtures. It cannot be too often said that the gravest danger accompanies the mixing up, for example, of chlorate of potash with substances capable of readily combining with oxygen. Many of the mixtures are easily exploded by friction, such as the trituration together in a mortar; and one of the most fertile causes of disaster is the slight friction that takes place when the stopper of a bottle is withdrawn or the lid of a cruet removed. Should there be a small portion of the mixture adherent a dangerous accident is almost certain to occur, and too often has one taken place with loss of life or limb. There is all the less need for amateur experimenting in this direction, seeing that there are nowadays on the market many such flash-light powders incapable of explosion by friction, the composition of which, however, is kept secret. But the price is comparatively low, so that little economy would be practised by the use of home-made powders. It is not, however, the storing or mixing up of these compositions that is attended with risk: their actual use is by no means free from danger. Heat, either from electricity or some burning body, has to be applied, and the numbers of accidents that have occurred, even to professional photographers, would surprise our readers could they count them up. The taking of flash-light pictures is often attended by a certain amount of worry and anxiety, and if any hitch should occur at a crucial moment the danger of a chance ignition is, in the hurry of the moment, lost sight of, and then it is that the accidents occur. The whole operation is almost as dangerous as playing with gun-powder in close proximity to a naked light. Anyone would think that foolhardiness, yet there is scarcely any difference between the danger of the two cases. Some operators who, in their own experience or their knowledge of what has happened with others, emphatically decline to use anything but the powdered metal alone. Some firms even will not undertake flash-light work at all on account of the danger. Nevertheless, under suitable simple precautions, the danger is reduced to a small minimum, and all that is needful for success is to see that the powders are in good condition. To assure this they should always be stored in well-stoppered bottles to keep them from the air as much as possible, for partially oxidised magnesium or aluminium will ignite with far less freedom than the freshly comminuted powder. Even the particles of the latter are always liable to an excessively fine coating of grease, which slightly reduces their ready ignition, so that their possibilities in this direction are increased by a preliminary washing with ether or benzol. It may be remarked that the powders should be very fine, so as to render the explo-

sion as rapid as possible; specially finely-powdered magnesium can be bought, but it costs almost 50 per cent. more than the ordinary. The object, of course, is to offer the largest amount of surface in the briefest time. We may describe the method adopted with this end in view by a professional of our acquaintance. He finds the powder has a tendency to clot, as it were, in falling, and to obviate this he mixes a little lycopodium with the powdered metal.

* * *

Rus in Urbe.

There are so few places within easy reach of our busy Metropolis which preserve their natural beauties; unsullied by bricks

and mortar and the moil and toil of commerce, that we are apt to become very jealous of any wanton encroachment upon our already dwindling beauty spots. The painter and photographer are especially interested in the preservation of natural scenery so far as it can be preserved in these machine-driven days, and they will always unite in any protest which may be called for against the advance of the utilitarian despoiler. Such an occasion has arisen recently in that charming riverside pleasure haunt loved by Londoners and known as Kew. Any one who has been there knows what a charming walk there is along the towing-path which bounds one side of the famous gardens. Strolling along that path, with the quiet river flowing at one's side, it is almost possible to forget that within a stone's throw are streets rendered unbearable by the presence of electric tramcars, motors, and bicycles. But there is another reminder of things commercial even closer still, for just across the river is busy Brentford, with its gasworks and other charms. But these have been screened from view by the presence of three green islands, or eyots, and the prospect was unimpaired. Two of them were long ago acquired by the Corporation of Richmond, and thickly planted, for their use was recognised, and their assistance in hiding the ugliness of the Brentford shore was encouraged. But the third island, the highest up-stream, belongs to the Steam Tug and Lighterage Company. It is at present bare, except for the osiers which fringe its margin, but it could easily be planted with trees like the two other eyots so as to add its share to the picturesque, and at the same time hide away a little more of Brentford. But the owners have another purpose in view regarding it. They have applied to the Thames Conservators for permission to enlarge the island and to construct upon it a dock for repairing and building barges. In short, the idea is to plant in the middle of the Thames, at one of its prettiest and most frequented spots, not trees, but a noisy yard which must by its nature constitute both an earsore and an eyesore. Happily, this outrage cannot be perpetrated without the consent of the Thames Conservators. It is for them to say whether this island, which lies immediately opposite Queen Elizabeth's lawn, and close to the riverside entrance to Kew Gardens, shall be disfigured in the way proposed. It would be bad enough if such a course were considered necessary in order to carry out some scheme of great importance to the nation, or even to the district to which the island belongs. But this is a private commercial undertaking which will possibly swell the dividends of the company concerned to a slight extent, while it will utterly destroy the charm of a playground which is common property. Photographers will be among the first to oppose, so far as it lies in their power, this attempt to mar the beauty of the river at Kew.

THE Royal Photographic Society's House Exhibition.—The Secretary of the Royal Photographic Society has notified us that M. Demachy has consented to leave his gum prints on exhibition at 66, Russell Square until Saturday, July 23, instead of July 9, as previously announced. Non-members will be admitted from 11 a.m. to 7 p.m. on presentation of visiting card.

THE PRESENT STATE OF THE PHOTOGRAPHIC LABOUR MARKET.

It will be remembered that, some weeks back, we directed attention to the present state of photography, with reference, more particularly, to employés or those who might be contemplating entering its ranks professionally. We then suggested that parents and others should hesitate before apprenticing young people to a business in which, at the present time, the labour market is very much over-stocked. Also that others of a mature age should duly consider the matter before entering the business. Since that article was written we have been making inquiries in different directions, and we are sorry to say that we find things in an even worse condition than we had surmised they were. We have more than once referred to the fact that the advertisements appearing in our pages—"Situations Wanted" and "Situations Vacant"—week by week, give a pretty fair indication of the state of the labour market. So they do, but only to a limited extent. A better criterion is the number of applications that are received by those who advertise for assistants. Many of these are addressed to our office, and it is surprising the number of letters that come even when what may well be classed as a quite nominal salary is offered.

To give some idea of what some persons will, or perhaps are compelled to, accept for their services we will cull from some of the advertisements that have appeared during the past few weeks. First, "Situations Wanted": "As General Assistant.—First-class Operator; good printer all papers; good reference; ten years' experience; salary 25s." "General Assistant.—Ten years' experience; four years in last situation; salary 30s." Here is another: "Young Married Man with twelve years' experience; good operator, retoucher, etc.; copyist and enlarger; reference to present employer; 30s. a week." We have specially quoted these cases out of many others, because in each the advertisers have had ten years', or more experience, and have good references, and yet they are seeking employment at what, at one time, would have been considered most ridiculous salaries. It does not say much for the future of employés if, after ten or twelve years' experience in the business, the above salaries only can be commanded.

Now, let us take a glance at the columns referring to "Situations Vacant," and see the salaries there offered by employers. Here are a few examples: "All-round Man; must be energetic; Wages £1." "First-class Operator and Retoucher.—Clever at posing, and good with children; good worker in black and white preferred; wages £1 5s." Fancy all these requirements for this sum. "Wanted, General Assistant; good retoucher; salary £1 a week." "Required, competent to supervise operating, developing, thorough all-round knowledge essential." For these qualifications the handsome sum of £1 a week is offered. "Wanted, General Assistant, all-round, and not afraid of work; salary 25s." The "not afraid of work" would suggest that plenty of it is expected for the munificent salary offered. "Wanted, Out-door Operator; must be quick, and understand his business; salary 30s." "Smart Retoucher and Operator, not under 25, for branch; salary 25s."

The advertisements just quoted indicate the salaries that some employers expect to get fully accomplished and skilful employés for, and, presumably, they do get men that answer their purpose for the sums named, for we find, unfortunately, that there are some anxious for employment at those rates. This brings us back to the subject we have more than once dealt with—namely, what

is the future prospect for photographic employés?—more particularly if we take into consideration the assertion, often made, that a man is "too old at forty." It should be mentioned here that in the majority of instances where these low salaries are paid Sunday work is required, hence the employé has to work seven days a week for his miserable pittance, which is far less than an unskilled day labourer is, by his trades union, allowed to accept.

We may add another illustration of the present state of the labour market. Not long ago an advertisement appeared in our columns, and a similar one in those of a contemporary, for an experienced operator to take views for picture postcards. We are informed that the two advertisements brought something like two hundred replies from persons anxious for the appointment. A very large proportion of the replies, we are informed, were from skilful photographers of long standing; and a not inconsiderable number from amateurs who are evidently intent upon entering the profession. Be that as it may, it shows that, apart from them, there are at present plenty of highly skilled workers anxious for employment.

In the foregoing we have only been referring to the male sex. If we turn to the advertisements of female workers we see that things are even worse, as witness the number of receptionists, retouchers, spotters, and the like who at the present time are seeking engagements. In the "Situations Vacant," for females, the advertisements are chiefly for apprentices to learn the business with or without premiums, but without payment in the shape of wages—or with merely nominal ones—for a term of, usually, three years. What is their prospect after they have served their term of apprenticeship? Very poor, we opine.

In the above, it may be thought, we have taken a pessimistic view of the situation, but the fact is it exists. Will it be improved in the future? Improvements are being continually made, alike in processes, material, and appliances, all tending to simplify the working, so that less skill is required in the working of them. All this simplification in working tends to more competition, particularly in the labour market. Of course, the salaries referred to above must not be taken as typical of those paid by high-class houses to gentlemen with high artistic abilities, but here even the labour market is over well supplied, and the salaries now paid are nothing like those that obtained in former times, and there is still a downward tendency in this direction. We once more advise those who contemplate entering the ranks of professional photography to hesitate before taking the step, for if they throw up their present avocations they may find to their cost that in grasping at what may prove a shadow they have lost the substance.

A MAN who takes the worst view of everything is not necessarily a pessimist. He may be an amateur photographer.

MR. JOHN BARTLETT recently read an interesting paper, entitled "Has the Brain a Photographic Function?" before the Photographic Society of Philadelphia. This will be found in another column. He described his personal experiences of a peculiar nature, in the way of visual impressions, which, while perhaps not of value in a photographic sense, might still be interesting. Impressions on the retina, he said, bear close analogy to those on photographic plates. The phenomena which he experienced are seen as things in space, whether originally formed on the retina or propagated by the brain, it would be difficult to determine. Among others, figures of definite geometrical form with frequently intricate patterns, like Turkish rugs, were seen, with beautiful gradations of colour and continual changes of outline. The projection of these images was involuntary, and entirely beyond control. Other views in the nature of pictures were seen, always of a pleasing nature.

NEW METHOD FOR THE PRODUCTION OF PHOTOGRAPHS IN COLOURS.

method forming the object of this communication is based on the following theories:—If a collection of microscopic elements, of a transparent nature and coloured respectively red, orange, green, and violet, be spread on the surface of a glass plate in the form of a single thin coating, it will be found, when the intensities of coloration of these elements and their number be correct, that the coating so made does not appear coloured when examined by transmitted light, and also that the coating absorbs a fraction only of the light transmitted. If light rays in passing through the elementary screens, of red, orange, green, and violet, reconstruct white light, if the number of surfaces or elementary screens for each colour, and the intensity of coloration of these, are in accordance with the relative proportions of those found in white light. This thin trichromatic coating being formed is then coated with a sensitive panchromatic emulsion. If the plate so prepared is submitted to the action of a coloured image, taking the precaution to expose through the back of the plate, the luminous rays pass through the elementary screens, and undergo, according to their colour and the screens they encounter a variable absorption before having any influence on the sensitive coating. By this means a colour action should be effected which acts on the microscopic elements and which makes it possible to obtain, after development and fixing, coloured images in which the tones are complementary to those of the original. If, for example, we take a portion of the image which is coloured red, the red rays are absorbed by the green elements of the coating while the orange and violet elements allow the passage of those rays. The coating of panchromatic gelatino-bromide emulsion will therefore be acted on beneath the violet and orange screens, while the remaining unaltered under the green screen.

Development reduces the bromide of silver sensitive coating, and so makes the orange and violet portions of the image, and the green portions appear after the plate is fixed, because the emulsion covering them has not received light, and so is transparent after fixing; the result obtained in this case is therefore of a green colour, which is complementary to the red rays dealt with. Similar phenomena are produced with other colours, as under the action of green light the green screens are masked and the coating would appear of red colour, with the use of yellow light the image would appear violet, and so on in like manner with other colours. It follows that with a negative showing complementary colours obtained in this way it is possible to obtain with plates prepared in this manner positive prints which will be complementary to the negatives, i.e., reproducing the colours of the original. Also, after development, and before fixing of the negative image that image may be reversed, and, by the known processes, a positive image may be obtained showing the colours of the object photographed.

The difficulties we have met in the application of this method are numerous and considerable, but the results obtained show that those difficulties may be overcome. It will suffice if we indicate a few of the more important conditions, showing the delicacy of the problem before us. A coating must be prepared composed of microscopic screens, orange, green, and violet, which coating it is necessary should adhere to its support, be extremely thin, that the coloration of these microscopic elements or screens should be exactly determined as regards intensity, quality of colour, and the number of elements of each kind. It is also necessary that these colours should be stable, that they do not diffuse, and that there is no superposition of colours or elements, nor gaps between them. It is further essential that the photographic sensitive emulsion should be orthochromatised in a manner which shall not falsify colours, and that this orthochromatism should be in relation to

the nature of the emulsion and the colours of the elementary screens. This coating of emulsion must also be of a special nature to avoid diffusion, and the manipulations, development, exposure, etc., must be of a nature suitable to these preparations. The simple enumeration of some of the conditions necessary to be fulfilled shows how essential are care and method to the success of such processes.

This research is not entirely finished, but we indicate hereunder the practical position to which we have brought the process at the moment. We first separate in potato starch and by the aid of apparatus made for this purpose, the grains having a diameter of from the fifteenth to the twentieth thousandth part of a millimetre. These grains are divided into three parts and coloured respectively red-orange, green, and violet, by the use of special colouring matters and by a process too prolonged to describe here. The coloured powders so obtained are mixed, after complete dessication, in such proportions that the mixture shows no dominant tint. The resulting powder is spread by a brush on a sheet of glass covered with an adherent or sticky coating. With suitable precautions we obtain a single coating of grains all touching and without superposition. We then stop by the same process of powdering the spaces which may exist between the grains and which would allow the passage of white light. This stopping is accomplished by the use of a very fine black powder, as, for example, charcoal. We have by these methods formed a screen in which each square millimetre of surface represents two or three thousand small elementary screens of orange, green, and violet. The surface so prepared is isolated by a varnish possessing a sign of refraction as near as possible that of the starch. This varnish must also be as impermeable as possible, as it is coated with a thin layer of panchromatic gelatino-bromide emulsion. Exposure is made in the ordinary manner, in a photographic camera, taking the precaution always to turn the glass side of the plate to the lens in order that the light may pass through the colour particles before reaching the sensitive emulsion. The necessity of employing emulsions of an extremely fine grain, and in consequence of lower speed, and the interposition of a coating formed of a system of microscopic screens, render the necessary exposure longer than for ordinary photography. Development is performed in the same manner as ordinarily, but, as we have said, if the negative be fixed with hyposulphite a negative is obtained which shows by transference colours complementary to those of the object photographed. If it is desired to obtain correct colours we must, after development, but without fixing the image, proceed to reverse it by dissolving the reduced silver, and then by a second development reduce the silver which has not been primarily acted on by the light. We see then that by simple manipulations little different from those used in ordinary photography, it is possible to obtain with these special plates, prepared as indicated, the reproduction, by means of a single plate and a single exposure, of objects in their natural colours.

A. AND L. LUMIERE.

SIR ROBERT BALL, who was sixty-four years old on the first of this month, has his name enrolled among Dublin's distinguished natives, and belongs, therefore, to that great galaxy of men born in one or other of the capitals of England, Scotland, and Ireland. Good physique comes from the provinces—our police are here credible witnesses—but the brain of England is preponderantly metropolitan. Another astronomer, by the way, is Dublin-born, Lady Huggins, her husband—true to the Capital rule—being a cradled Londoner. Sir Robert Ball has written about another ball a book called "The Earth's Beginnings"; and a surface plausibility for the astrologist may be scented by some in the fact that the very same day, sixty-four years ago, that saw the birth of Sir Robert saw also the birth of Mr. Edward Clodd; and Mr. Edward Clodd, too, wrote a book about "The Childhood of the World."

PLATINOTYPE PRINTING.*

PLATINOTYPE paper is easy to manipulate, the process is quick-printing (taking half or a third the time required by silver printing-out paper), and the prints are absolutely permanent, the image being of platinum—a metal which is attacked by scarcely any known reagent—upon a support of pure paper. An additional recommendation is that a platinotype print can nearly always be saved, however badly over or under printed. The platinotype process will also do ample justice to almost any negative. A small disadvantage of the process is that the printing has to be done by daylight. Platinotype paper was invented by Willis in 1873, improved in 1878, and further improved in 1880. The platinum was at one time added to the paper in the process of development, but it is now upon the paper, and the troublesome and expensive operation of introducing it in the course of development is abolished. The paper must be kept quite dry. It is, therefore, supplied in hermetically sealed tins, and the paper on removal must be kept in proper storage boxes containing chloride of calcium, which absorbs any moisture that may be present in the storage box. This keeps the paper so dry that it requires careful handling to prevent it from cracking, a defect which will show to the end of the process. Everything used in connection with platinotype paper should be perfectly free from damp. Use an indiarubber sheet at the back of the paper in the printing-frame to prevent atmospheric action. The print may be stored in the calcium tube for some weeks, but it is not advisable unduly to delay developing. The sensitive side of the unprinted paper is of a bright lemon colour, upon which the image turns to a purple colour when sufficiently printed. All but the finest detail should be seen, and the print must be examined in very weak light.

The following formulæ are for black tones:—

Ilford Company—

Potassium oxalate	2 oz.
„ phosphate	½ „
Water	14 „

Dilute with equal quantity of water.

Platinotype Company—

Potassium oxalate	2 oz.
Water	7 „

Dilute with twice the bulk of water.

Eastman Company—

Potassium oxalate	1 oz.
„ phosphate	½ „
Water	10 „

It does not appear to matter how strong in oxalate the solution is. I have used the first bath, which gives very satisfactory results, three times as strong and at half the strength, but there is little difference between their results, given a correctly timed print. If the developer produces a print of a brownish colour, it can be made to print blacker or blue-black by acidifying the bath with a few drachms of oxalic acid. The developing solution may be used repeatedly, a used bath being, in fact, better than one freshly made. But when using an old developer one must see that there is no scum on it, for this causes little immovable flecks of black to form on the print. The image comes up quickly upon immersion in the developer, but the print should not be removed until the desired strength is reached. It is then put into the following clearing bath without intermediate washing:—

Hydrochloric acid...	1 oz.
Water	60 „

One effect of clearing the prints is to turn the bath yellow, and a print is not properly cleared until it ceases to colour the acid bath. Traces of yellow in the bath indicate that the iron has not been cleared from the print. At least three clearing baths are necessary, and the last bath must remain

perfectly clear. The print does not change in the acid bath except in so far as it loses its yellow colour.

The developer, used cold (about 60 deg.), should produce agreeable black tones; too warm or too old and degraded developer or damp paper show themselves in a brownish print.

The cleared prints require washing in three or four changes of water, and may then be dried between blotting paper. The addition of a pinch of washing soda to the washing water, neutralise any acid that may be left in the paper, has been recommended; but in order to be quite sure that no acid remains, the water that drains from the print may be tested with blue litmus paper. The method of producing black tones by a hot bath (for which a paper is made specially) seems to have very little to recommend it; the results are no better than those of the cold bath, and the method is more troublesome. Before leaving the subject of black tones, I must call attention to the platinum printing-out papers, made by Jacob and Hardecastle. This paper, which is slow, is printed out under the negative, and is cleared in hydrochloric acid of 1 oz. water 80 oz. It is necessary to carry the printing much further than is required in the finished picture, as the image is much reduced by the clearing. The process is a long one, and the result is not equal to the developed print.

Sepia tones may be obtained by many methods, but I will refer first to the papers made specially for these tones. The Platinotype Company make a paper for development in a lemon bath. This paper is much more sensitive than ordinary black-tone paper; it requires more careful handling, and should be examined only in the weakest possible light; otherwise manipulation is as simple as that of black-tone paper. Sepia paper is not supposed to keep very well before development, but I have found that when four or six months old it gives very much nicer tones than the new paper. Two prints, one on new sepia paper and the other on paper five or six months old, are before you. The tone of the old paper is cold and desaturated, while that of the new tends towards a hot brown colour. The developer for the Platinotype Company's sepia paper is a special one, sold by the Company. It is used at a temperature of 150 deg. to 160 deg. F. I have, however, developed sepia prints in the ordinary black-tone developer, with apparently satisfactory results. Sepia papers should be cleared in a bath by themselves, and not in the bath used for ordinary papers. Another sepia paper is made by Jacob and Hardecastle, cold development with special salts, but a print on this paper developed with the ordinary cold developer is upon the wall and the result is quite satisfactory.

Sepia prints may also be made by introducing chloride of mercury into the oxalate developer. This method gives a fine range of colours from a dark, rich sepia to golden brown. I cannot speak as to the permanence of prints made in this way, as I believe that when any additional agent is introduced into the oxalate bath, the permanence of the resulting print is more or less interfered with. I think, however, we are justified in obtaining these colours by these methods, provided we take the care of the prints we should bestow on water-colour pictures. The prints will certainly retain their colour for a considerable time, and while they do so they are generally very agreeable. A disagreeable dark brown will be obtained, however, by using a very strong solution of mercury, but with the following formula, introduced by Mr. C. F. Inston, the results are quite satisfactory:—

A.			
Potassium oxalate	1 oz.
Water	7 „
B.			
Potassium citrate	75 grains.
Citric acid	120 „
Mercuric chloride	45 „
Water	7 oz.

* A condensed report of the third of the series of practical demonstrations given before the Royal Photographic Society.

Two solutions are made separately, and used in equal portions. The solutions should be used cold, and should be touched as little as possible with the fingers, as the mercuric chloride is a strong poison. One characteristic of this mercuric chloride developer is its power of bleaching the print, of which advantage can be taken in two or three ways. A slightly overexposed print from a flat negative developed in the mercury gains considerably in contrast, and is much better than developed in the ordinary oxalate bath. The bleaching action takes place particularly in the more delicate parts of the print, darker portions remaining practically untouched. Developers in which the mercuric chloride is present in incorrect proportions give undue contrasts, and sometimes double tones. It is developed in this bath should be cleared in a bath slightly weaker than that used for the black prints, because the mercury reduces the mercury, and, if the print remain long in the bath, it entirely discharges it, the light tones being almost completely bleached. A suitable clearing bath consists of hydrochloric acid $\frac{1}{2}$ oz., water 60 oz.

Mr. Alfred Steiglitz has utilised this action of the clearing bath for the improvement of prints from flat negatives. His method is to over-expose the print, develop in the oxalate and clear in a strong acid bath until all traces of the mercury disappear. The result is a brilliant print with black and white contrasts. Assuming a warm tone is developed upon a paper intended for black tones, the paper is slightly under-printed and developed in a heated bath. The point is illustrated by some prints on ordinary paper, developed (1) in a cold bath, (2) in a bath heated to 96 deg. F. (3) in a bath at boiling point. This experiment showed that whereas in (1) the print has been under-exposed and is unrepresentative, developed cold, in (2) with the developer at 96 deg. F. the print is full of vigour and detail, and the colour is agreeable warm black; while in (3) with a boiling developer the print has the appearance of an over-exposed print. The experiments were made with one print divided into three parts, and they show that almost any print can be saved—further, that if a warmer black than a cold developer gave wanted, one need only under-print and develop with hot water.

Glycerine affords tremendous possibilities to the platinotype process. By coating the print with glycerine, and then applying the developer locally with a brush, it is easy to retard or to eliminate portions of a print. Where very black tones are required, the glycerine may be blotted off. The glycerine-developed print is cleared in the usual bath, which should be helped in its operation by gently wiping the print with a tuft of cotton wool, otherwise the development may continue under the glycerine before the acid can get through. Platinotype prints may also be toned with catechu, the bath being used as follows:—
Packham, who described the process to the Society, said: "A metallic deposit on a platinotype print has a singular affinity for the organic substance known as 'catechu,' which for years has been used for dyeing textile fabrics." There is, of course, a difference between toning and staining a print. It is possible to stain a print by saturating it with almost any coloured liquid, but in toning the paper is generally required to remain white, and the image only to change colour. Packham claimed that catechu would change the colour of the platinotype print, because of its affinity for the deposit, without staining the paper. If, however, a print be allowed to remain in a catechu bath too long, or if the bath be used too hot, there is a staining of the paper. Properly done, the toning gives a pleasant colour. The catechu does not intensify, but rather softens the print. The solution is supposed to be used at 60 deg. F., but it is not absolutely necessary, I believe, to keep it quite so hot. A print toned in this way, if unsatisfactory, may be washed with soap and water and hung in the air, or put into a weak hydrochloric acid bath to restore

its original colour. I have some prints which were treated with hydrochloric acid, and changed from a disagreeable red colour to a more agreeable tone.

Uranium Toning.—This method is rather dirty and disagreeable. The colour is somewhat fugitive, and frequently unpleasant, and one is likely to get staining instead of toning. If one does not like its results, however, the print can be returned to the developer and brought back to its previous state. Uranium toning also intensifies, and a weak print may sometimes be saved by this process. A long range of colours may be obtained, from sepia to red-chalk, and greens and blues are also obtainable. The formula I have used is the following:—

A. Uranium nitrate	10 grains.
Glacial acetic acid	1 drachm.
Water	5 oz.
B. Potassium ferricyanide	10 grains.
Glacial acetic acid	1 drachm.
Water	5 oz.

Mix separately until dissolved, combine and add sulphite of soda, about the size of a pea. The prints soon turn a red colour. Prints intended for uranium toning require special care in development and clearing. The development should not be prolonged, and it is essential that the iron salts shall be completely removed. To ensure this, five baths should be used, or one extra after the last bath appears quite clear of yellow stain. They should then be washed for about an hour in six changes of water. It is best to dry the print before toning. For red tones the print should be a little under-exposed, as considerable intensification occurs in the bath—a somewhat prolonged immersion being required.

For blue tones, the same formula is used, but the print is left in the clearing bath for only ten seconds before being placed in the uranium bath. The print will gradually turn blue, and, when rather darker than required in the finished picture, should be cleared in a weak acid bath composed of:—

Hydrochloric acid	$\frac{1}{2}$ oz.
Water	120 "

It is then washed in two or three changes of water. This presupposes that one intends at the outset to get a blue print; but if we desire to convert a brown print into blue, it is immersed in—

Sulphate of iron	$\frac{1}{2}$ oz.
Water	20 "

when it will gradually turn blue, and it only remains to wash the print in water. In the first blue process, the reason for placing the print only for a short time in the clearing bath is that a portion of the iron shall be retained in the print, for it is the action of the uranium and iron together that produces the blue tone. The shorter the immersion of the print in the clearing bath, the bluer will be the result, while the longer it is in the clearing bath the greener or browner will the print become.

E. T. HOLDING.

In the discussion that followed the foregoing demonstration Mr. F. T. Beeson said that in order to judge when platinotype paper was sufficiently printed it was necessary to keep a careful watch upon it. A little practice soon enabled one to judge when it had reached the right stage, but after that stage had been passed it was very difficult to tell how much the paper had been over-printed without an actinometer. With regard to the hot bath process, which he had been compelled to use when the cold bath process was not known, it had some advantages, and it was often used by professional photographers. In this process development was very rapid, a quality which, to the professional, was of great advantage. The disadvantage of the hot bath was that, having to be maintained well heated, it rapidly evaporated; and especially was this disadvantage experienced when one tried to work with a small quantity of solution. It was a good plan to heat the solution in a sauce-

pan before the developing was commenced. He advised the use of a porcelain dish, in preference to one made of enamelled iron, and if a piece of asbestos board were placed between the gas flame and the dish, it would prevent the latter from cracking. With regard to the repeated use of a developer, the question was not so much how long the solution had been used as how many prints had been developed by it. He thought it would be dangerous for the beginner to develop too many prints with a small quantity of solution. With regard to the addition of mercury to the developer, Mr. Holding appeared to have found that Mr. Willis asserted some years ago—namely, that the addition of mercury to the developer tended to give a disagreeable brown tone, and a warmer tone in the half-tones than in the shadows.

PHOTOGRAPHY AS A PROFESSION IN THE UNITED STATES.

SECOND ARTICLE.

IN outlining a plan for organising photographers for the protection of their business interests and to ensure a decent living for them by eliminating as far as possible over-competition, as is done in all other professions and trades, I was rather handicapped by this proposition, one that I felt the more I thought of it to be fundamental—that any scheme for the betterment of photographers must protect the very weakest individual who is trying to honestly earn his living by photography. But on the other hand there was another point almost as urgent—namely, the relationship of the public, who must be given something in exchange for the present questionable blessings of free competition among those catering for their trade. All other professions or trades endeavour to balance matters by guaranteeing a better quality of service than previously, and it must be admitted that on the whole this is true, so photographers can do the same.

Here, then, are conditions to be fulfilled. We must protect as far as possible all those now engaged in photography, and we must raise the standard of the work turned out by the average gallery.

It is easy enough to devise a plan to kill off the weak members of the fraternity, in fact I could point out half a dozen ways in less than an hour, but, outside the morality of the proposition, it would be poor business policy, as an equal number would bob up out of the woods in a very little while. No, the remedy lies in limiting entrance into the ranks by insisting upon higher educational qualifications and an expensive training from would-be photographers, just as is demanded from other occupations.

In their present disorganised condition, photographers are in no fit shape to go before State legislatures and demand the enactment of laws creating their craft into a profession by the enforcement of a college career on would-be photographers, and, since it is a mixture of a one-man business and factory system, the help are unable to organise it into a trade. It therefore looks to me that the feasible plan at the present moment is to combine the suitable features of both profession and trade union, leaving higher ambitions to the future when photographers are more perfectly organised.

Again, knowing the shortsightedness of the average man, who thinks more of present needs than possibilities of a few years hence, it is essential that the proposed plan shall give some tangible, immediate benefit, while lack of connection with it shall be seen in present loss. This statement may appear to many to be an outrageous libel on the human race, but the fact is beyond dispute and all human institutions are perennial proof, for government, it is now admitted, was originally in-

stituted, and is to-day fundamentally constituted, for the great purpose of protecting that portion of wealth which is aside for future production for the needs of the race. In other words, the unthinking, improvident many have to be coerced for their own good by the thinking few.

Immediate advantage therefore to the average man who participates in the proposed organisation is an essential feature of the scheme, and this in turn must be the principal factor in the structure once it is complete. We are now therefore in a position to sum up the broad principles that must be kept in mind in devising a plan for the present and future betterment of professional photographers. In the first place it must be restrictive, that is, make entry into the profession difficult by demanding higher education and technical qualifications from would-be photographers. It must be protective, not only of the very best workers in the ranks, but also of the poorer because the interests of those who benefit by competition are best served when there is in the market a goodly number of indifferent workmen looking for positions. The buyer of labour, whether employer or general public, offers such workmen low prices because of their unskilfulness, but when dealing with good workers they insist they can buy the labour of the better workman for so much less, but conveniently ignore the different quality of the service. The strength of a chain is measured by the weakest link, hence there is much wisdom in the policy of the trades unions in protecting the weak workmen, and so necessity has evolved the natural law that commands every individual to defend the members of the group to which he belongs against all comers.

Weighing carefully all these premises I was forced to the conclusion that a plan of giving certificates was the one to be adopted. As regards the employers, the idea first of all to grant from an authoritative source a diploma of merit—as is given to other professional men. The idea is this—a document hung in a conspicuous place, following the example of doctors, dentists, lawyers, etc., has a psychological effect on the community in giving confidence in the ability of the holder. Of course it is no guarantee that the photographer is the best man in town, any more than the doctor's diploma proves him to be a good physician, but it is an assurance that he ought to be, for at one time he knew enough to be efficient, and in this light it is accepted by the public. Confidence between photographer and customer is a great thing, and a certificate of competency is worth much to any man. At first will be necessary to pitch the standard covered by these certificates rather low, but year by year it can be added to so that even the weakest man will be forced to make advance. Improvement is against gravity, it is propulsion and competition that lifts to a higher plane, so the examining board should guide the poorer workman on his upward course by the application of a little judicious pressure. But it must never be forgotten the aim of the scheme is not to kill but to help.

In the same way certificates shall be granted to employers based on their actual ability as reported on by previous employers.

I recommend that all certificates be of three grades at first, namely, ordinary, honour, and extra honour. The ordinary grade should certify the possession of technical skill only, honour certificates will be granted to those who show knowledge of the theory of their craft, as well as possession of skill. As soon as conditions permit of it the ordinary grade should be made to include the honour grade, and then the present extra honour certificate would become the honour certificate of the future.

After weighing all sides of the question I am decidedly of opinion that certificates should be granted for one year only so as to prevent unprincipled individuals from securing a certificate and then for monetary personal gain carrying

some scheme that would be detrimental to the profession as a whole. I would be very, very chary of granting certificates for life to any man.

As soon as it was found possible I would link the employers' and employees' certificates together, by making it a condition that certificated employers hire only certificated help, and the latter work only for those who are similarly qualified. This is the crux of the whole problem, for the instant such a condition of affairs is feasible, the fraternity get a firm grip upon would-be entrants into the profession. In the case of young people they can demand suitable educational qualifications, while they can head off adults who want to start in business by making it exceedingly difficult for them to secure competent help.

A very essential feature of the scheme I consider to be the establishment of an employment bureau with prompt service for the holders of certificates, and no others, this being one of the immediate benefits I have referred to.

In drafting this plan it will be noticed I have tried to combine such features of both professional organisations and trades unionism as seemed applicable to photography as it is at present constituted. It is not set before the fraternity as a perfect plan by any means, but rather as a possibly practical proposition that may work, or at least lead to the evolution of a better one. The fact that it was seized hold of with enthusiasm by the Illinois photographers shows it possesses some merit, and my daily correspondence assures me that photographers feel the need of some organisation based largely on economic principles. Conventions have in the past done much for the education of the photographer to the direct benefit of the public in providing them with better pictures, but the financial status is as bad as it ever was, if not worse.

In the next article I will outline the methods of granting certificates and the qualifications I consider necessary.

F. DUNDAS TODD.

WHERE ARE WE GOING?

[Translated from the "Revue Suisse de Photographie."]

In running through the photographic publications of the last few years, and more especially on visiting the photographic exhibitions, we have been stupefied by what has been submitted to the public. Landscapes, described as such in the catalogues, which appear to have been taken at midnight in foggy weather; heads of young girls with grandmotherly features; portraits of white men disguised as niggers, sweeps, etc. And these are commended by critics as prominent works of art and as—the expression of nature. But we venture to reply that it is usual to dress before going into society, to wash one's face and remove carefully any trace of uncleanness. If in a photograph we represent one cheek like a sweep's, we falsify nature, and there cannot be any pretence of "expression of nature." Again, if by faking we suppress, in a landscape, trees, roads, houses, etc., which may be found inconvenient, and if we add to the bargain, by putting in with the brush, objects which do not exist, we no longer have any right to speak of a representation of nature.

It may be objected that the modern photographer no longer consents to be tied mechanically to his subject, and that he is an artist, who wishes to express by photography the impression he has received in contemplating the subject before him. This is where the shoe pinches. Some object to being called photographers nowadays. The name horrifies them. They are artists, impressionists! But, in painting, impressionism often leads to extraordinary exaggerations, even though the painter has numerous valuable aids to fall back upon, such as harmonious colouring, thorough professional education, and, lastly, a certain licence in drawing, because the work is done by

his own hand. To what extent are not these exaggerations increased in photography? Colours are not available, and the operator is always more or less bound by the drawing of the negative, although certain clever gum workers pretend they can produce a winter landscape from the negative of a young girl, which fails to please them. The ultra-modern photographer is no longer content to present an exact rendering of nature, which he has endowed with personal feeling and great artistic value by the perfection of his work, the judicious selection of the point of view and the printing process. He wishes to create, create absolutely, like the painter. If he feels he has that creative power, why does he not free himself completely from the trammels of photographic apparatus, to which he must remain a slave despite all dodges, and create his pictures with his own hands? But this he cannot; the photographic support is indispensable for rendering "his impressions." A few years ago there was a great fight over the question, Is photography an art? Many demurred, some classed it with the recognised fine arts, and the wisest defined, and still define it, an art, yet one of a special kind, possessing some points of resemblance with painting, but which, nevertheless, is very different. He who seeks to imitate painting, or engraving, by means of photography, does the work of a plagiarist, and degrades the photographic art to mere simulation.

Let there be no misunderstanding, however, as to our intentions. We do not desire in the least to detract from the artistic value of photography; we are only aiming at the abuses of ultra-up-to-date photographic trickery. What is this trickery? We think we can expose it in a few words, by means of the prevailing improper use of gum bichromate. Gum bichromate, in the hands of a clever, conscientious worker, may be very serviceable. Its grain gives a softness of line which in many cases is far from displeasing. But, unfortunately, the process also lends itself admirably to dodging. By its means nothing is easier than reducing or intensifying the shadows in any part of the work. There would be no great harm in this, and nothing to say, if it were not exceeded. But gum bichromate also lends itself with great latitude to brush work, and when it is abused a grain of such size is left that all detail is eaten away. The ultra-up-to-date workers now offer gum bichromate prints in which the whites actually are spotted and sullied with large specks of black. There are no half-tones, and the shadows are black, or grey, without any detail. The entire print is freely worked up "with the brush," and it is labelled "An artistic study." A few years ago everybody's opinion would have been "terrible under-exposure!" To-day, through snob-bishness and fashion, it is thought very fine and quite artistic. Nevertheless, it does not dispose of the fact that in many cases the authors of these "works of art" would be in a sore quandary if they were asked to make a plain, normal negative.

This is the trouble of the gum bichromate and similar processes. They facilitate trickery to the detriment of technique. Nevertheless, technique causes photography to progress, whilst trickery does not. If the fuzzyites and up-to-daters continue to follow the path they have taken, and if they make more adept converts, which is probable, considering the snobbish character of the men, we fear that in the course of a few years we shall see portraits merely representing the end of a nose, one eye, a few high lights "perfectly placed," and the whole surrounded by the blackness of night. Have we not already been able to admire (?) such masterpieces in the most recent exhibitions of "photographic art"? Those who know how to develop suitably a normal negative, without over-exposure, or under-exposure, will then form an abject minority. Moreover, it will not be necessary to take trouble to get a good negative. The brush, sawdust, etc., will supersede with advantage all antiquated machinery.

But is it really believed that the production of these "frames" (we do not speak of photographs now, it is

too vulgar) is the acme of photographic art? We hope not, and we prefer to look upon it as an ailment of infancy, which will soon pass away. We do not fear to see photography emancipate itself from routine. We have warmly praised those who have had the courage to forsake their studios to photograph people at their homes, in their own surroundings, but on condition that they give us a true photographic portrait, not a spurious thing occupying a place somewhere between an under-exposed photograph and a bad engraving indifferently inked up. A small amount of fuzziness in some large landscapes or portraits does not offend us. But we should not go too far, and make light of the public by forcing upon them as "works of photographic art" enlargements from bad negatives, over-exposed and especially under-exposed, printed in gum bichromate (size of grain, 0.3 to 0.5 c.m.). If it pleases, anyone may make fantastic, tricky photographs now and then. It is occasionally very amusing. But do not imagine that such sketches are good photography.

As we are venting our spleen for once and may make some enemies, let us say a word concerning judges at photographic exhibitions. Most of these enterprises take care to add the epithet "artistic" to their names. It is very nice, but we will not repeat—yet there is ground for criticism in the selection of the judges. There we find a long list of painters, sculptors, engravers, and art critics, sometimes celebrated, sometimes obscure; but the names of capable photographers, professional or amateur, are frequently conspicuous by their absence. This is a great anomaly and injustice, but it harmonises well with the up-to-date "artistic" tendency. It seems to us that photographic work should be judged by photographers, people who know its technical difficulties and who can estimate it at its true worth. We do not deny the value of adding to the list a few painters or sculptors who take a friendly interest in photography (there are some, perhaps not many, who are its enemies). But most of this work should fall to photographers. We lay claim to it, and we wish that all the friends of photography would do the same, even to the extent of boycotting all exhibitions where the judges are selected outside the ranks of photographers.

But let us draw our lamentations to a close. We think our readers will find them burdensome enough for once. Yet we repeat that which we said at the beginning of this article: It is time someone raised his voice against the exaggerations of ultra-up-to-date photography.

DR. R. A. REISS.

HAS THE BRAIN A PHOTOGRAPHIC FUNCTION?

[A paper read before the Photographic Society of Philadelphia.]

THE study of the phenomena of vision, although it has no direct bearing on photography, is not altogether foreign to it. Some considerations, therefore, of a peculiar sort of visual impression connected with personal experience may be of interest if they are not of special value to the photographer who may have a scientific turn of mind. The impressions upon the nerve-fibres of the retina, of whatever nature they may be, bear a very close analogy to those upon the sensitive film. A picture is certainly formed there, which endures for an appreciable time, but whether this picture is directly impressed upon the cerebral substance, resulting in what we call conscious vision, cannot as yet be determined.

Impressions once made and seemingly obliterated may be redeveloped, as we, photographically, say, by the stimulus of some corporeal disturbance, in much of their original vividness and reality, but it would be a difficult question to determine whether in the revolution of the cerebral photograph an image is again impressed on the retina resulting in vision, by a reverse or reflex action. The writer sees no reason why the nervous matter of the retina, as part of or in direct communication with the brain, should not facilitate the flow of the nervous current to itself. I suppose most of us have had personal experience of the sort of appearances known as ocular spectra, produced by the impression of a strong light on the retina, and

which force themselves sometimes very obnoxiously upon us, even when we endeavour to shut our eyes against them. However, when they are moderate in their action they become an enjoyable study, passing through many singular and beautiful phases, and presenting a highly orderly and harmonious arrangement of form and colour.

The seat of these spectra is undoubtedly the retina itself, but whether they originate there or are reflexly propagated thither from the brain would be hard to say. Light or some extraneous disturbing force, it would seem, is necessary to act first upon the sensitive end of the optic nerve, but are we to attribute their production to molecular disturbance in the retina itself, or is the retinal stimulus the exciting cause for the cerebration? Might we presume to say that their production is part of that photographic process by which light acts chemically upon the retinal substance, and that there is a gradual restoration of that organ to its normal state of sensitiveness by the fading out of the pictorial impression? It is from this belief that I think my personal experience may be of some interest to photographers, if not to any one else.

But how are these impressions made upon the retina? Are they projected from something without, or are they mentally evolved? The phenomena, which I am about to describe, are seen as things in space like any other material things, but are they visual externalities? Are they not really objects in the mind's eye, though actually on the retina? I do not mean purely subjective and visionary, but real products of the brain or pictures made by the brain. There are certain peculiarities about these spectra which make them essentially different from visions or hallucinations. Often they have definite geometric outlines, and frequently form intricate patterns like the figures on a Turkish rug. The lines are sometimes dark on a light ground, and sometimes the reverse; negatives and positives of the same pattern. Sometimes they are very complex and most beautifully gradated in colour. They change from instant to instant, and do not admit of a very close study, even sufficient to depict them rapidly—else they might be quite a boon to any one designing patterns for the carpet trade; however, they always change on a systematic principle, and seem to have a law governing their formation not unlike the systems of crystallisation, each succeeding one being a variety or modification of its predecessor. They have a sort of fixed axis about which the transformations take place. It seems as though the agency, whatever it may be, had a very definite plan and a consciousness of what it is doing, however much concealed from our knowledge. This definiteness is an evidence, I think, that they are not the product of disturbed nervous condition of the perceptive. There is no co-ordination of action in hallucinations.

These pictures are not reproductions of objects recently seen, or probably ever seen before—memory pictures—but are quite novel in their structure and unexpected in their plan of presentation, and might, as I have said, be advantageously employed, could they be detained long enough to catch their fleeting beauty, for no effort of the will, at least not in my experience, can fix them. But this fugitiveness does not preclude them being observed and described *pro tanto* in general terms. They have an uncontrollable freedom of their own will, and seem to take a sort of malicious advantage of it in changing the combinations. I have frequently tried to fix their shapes by an effort of the will, but they ever changed "into something far more rare and strange" than my imagination had power of conjuring up. They appear to be painted on dark space or on light space by some invisible dexterous artistic hand. I shall not dwell longer on this part of the subject, though I know I could make it most interesting by more accurate description, my purpose being merely to direct attention to a particular phase of the phenomena which some might be inclined to call hypnotic vision and dismiss the subject with a sneer—and who can answer a sneer? These impressions about which I shall speak are not so vivid or eye-hurting in their manifestations as the ocular spectra, but may be studied with quite as much wide-awake observation. Indeed, when they present themselves, as they frequently do, quite unexpectedly and wholly independent of will power, they cannot be distinguished from actual visual impressions, and the beholder may believe that he sees them. And does he not? Though independent of the will they do not persist long, yet endure longer than the geometric figures, dissolving slowly like dissolving views in the magic lantern. I have frequently tried to make the presentations take forms accordant to my fancy, but no—like Glendower, I might summon up spirits from the "vasty deep," but they would not come

I did call them. They presented something always entirely new to my desire, something so unexpected, so delightful, that I suppose the desire to revel in the enjoyment of them weakened the power of the will to control their formation. Like the ocular spectra of some invisible ingenious painter seemed to be embodying

most people are not aware, until they question their experience, that they possess more or less the power of seeing forms and faces in the dark, not in absolute darkness, but when a faint halation of light is present. People not by any means visionary have told me of their possession of this faculty—for it is a faculty—and in many cases of amusement and delight when one is in perfect health and free of spirits, but under depression of mind their occurrence may be unwished for on account of their incongruity to the mental state.

"The mind in grief," as Shakespeare says, "being best pleased with shapes of things," for these images are sometimes of a most curious character, never in my personal experience of a hideous nature, nor in any way approaching the visions which Swedenborg describes as us with. But they are so persistent, so self-willed, so obtrusive at times, that one is tempted to say, "Take any shape but mine." Though produced involuntarily, they continue long enough to form definite shape and relation, and can in a measure be studied from different points of view, each angle of view, strange to say, like a real thing, changing properly the play of light and shade most beautifully. The vision of landscape (I ought not to say vision, but rather imagination) is not as frequent in occurrence as the sight of faces or forms, but the landscape is always more distinct and seemingly more real, though subdued in a soft peculiar light, "a light that never enters the sea or land."

The contemplation of these scenes is most delightful, the play of light and shade varying with every shifting of the eye, that is, they are both linear and aerial perspective. It is this peculiarity which I have persuaded us that they are real. It is only that judgment coming to our aid tells us—I was going to say—that they are the substantial fabrics of a dream, but these impressions are waking visions, not dreams. Call them waking dreams if you will, but do not put them otherwise than by referring them to a proximate cause.

Had I power of the poet I might delight you with a description of some of these wonderful pictures which have occasionally presented themselves, and had I the skill to portray I might shine as an artist. Unfortunately, I have not the faculty and art divine, but I think the great painters must have possessed something akin to this faculty, coupled with the gift to hold and fix the impressions. I remember reading that Goethe speaks of his delight in experience of this identical kind. So intensely, on one occasion at twilight, was a landscape presented to my view over a hazy background of meadow that at first I thought I was looking at a mirage—

"So pure the sky, so quiet was the air,
So like, so very like, was day to day.
But when I looked, no image still was there,
It trembled and it softly passed away."

This quotation is from Wordsworth, and I believe he wrote from his personal experience of this sensorial visual faculty. I am perfectly willing to admit that the imagination may interpret forms in themselves as finite as the expressions of realities; for even the most prosaic amongst us can see faces in casual blots, or pictures in clouds and in fire. But no such explanation is applicable here. These are involuntary impressions in which definite regularity and actual coherence and relations of parts predominate. The imagination is not called in to supplement or to eliminate parts, so as to isolate the image from its surroundings.

It is obvious that a regular geometric pattern or a coherent structure of pictorial intent cannot be suggested to the imagination by anything having no regularity, so that the question will force itself upon us how to explain this strange sensorial vision. What a maze we get into if we should attempt to explain the connection between the mental and spiritual organism, but what a wonderful study it is open. Is there some intelligence working upon our organism distinct from that of our own personality, whether external or internal in us? But this explanation might be objected to as ontological and outside experimental science. Or can the phenomena be explained in purely physical terms, as a quasi-image formed on the retina by the sympathy of the nerve-fibres with the brain, and their

impressions delivered back to the sensorium as that of a reality? Or another solution is suggested. Has the sensorium the power to combine symmetrically separate elements independent of the will to the formation of definite new patterns or scenes, or are these impressions nothing but the revivification of dormant hereditary concepts?

To produce a definite regular symmetric arrangement of lines, angles, lights, and shades, and a disposition of colours for the formation of distinct patterns, or pictures subject to geometric rules, and in accordance with the artistic laws of harmonious colour and composition, seems to imply a conscious producer which the ontologist would call the spiritual essence, or the psychologist mental cerebration. The one referring the cause to some super-sensual agent, the other to molecular chemical action of cerebral corpuscles. But with any explanation we must acknowledge that every event has a cause. Yet if the human will is subject to what appear to us the caprices or a more powerful will, the question of man's responsibility for his actions or credit for his mental achievements comes in to be accounted for. We do not feel specially elated with the consciousness that we may be nothing but inspired idiots after all. Philosophers as well as theologians have generally maintained that man is a moral agent, and that he has perfect freedom of the will, else he becomes a mere unconscious automaton controlled by an overpowering and arbitrary environment.

But what determines the will to a choice? Especially is the question involved when there is no predisposing bias to determine the direction of choice. The mind is a wonderful mysterious entity we are almost justified in calling a spiritual essence, but the impact resulting in visual perception (I mean here ordinary visual perception) is a physical manifestation, and as much a molecular disturbance, whether external or internal, and reflex in its action, as the impact of light upon a sensitive plate. The whole subject is one worthy of a study from a physical standpoint by one more capable of investigation than the writer, and should not be summarily dismissed with the proffered salutary injunction to the narrator:—

"A solemn air and the best comforter
To an unsettled fancy cure thy brains
Now useless boiled within thy skull!
There stand, for you are spell-stopped."

JOHN BARTLETT.

THE ADAPTATION OF THE FORTY-INCH VISUAL REFRACTOR OF THE YERKES OBSERVATORY TO PHOTOGRAPHY.

In the original design of the forty-inch refractor of the Yerkes Observatory no provision of any kind was made for direct photography; there is no guiding telescope to enable lengthened exposures to be given, nor photographic corrector to bring the actinic rays to a focus on the sensitive plate. Mr. G. T. Ritchey has overcome the first difficulty by means of an eyepiece magnifying about one thousand diameters, placed in the side of a double-slide carrier. "Knowledge," in describing this achievement, says:—"A small diagonal prism receives the light of the guiding star, and reflects it at right angles into the eyepiece, and this with its accessories are mounted on a slide, which can be moved to any desired position on the upper side of the rectangular box, and firmly clamped there, so as to assist in finding a suitable guiding star. The star is brought to the intersection of the crosslines in the eyepiece, and is kept there throughout the exposure of the sensitive plate. The observer sits with his eye at the guiding eyepiece, and his fingers on the two screws which move the slides, and thus he introduces any minute corrections of position which he sees are necessary. These corrections may be on account of either the irregular movements of the driving clock of the telescope, or more frequently from the tremours in the atmosphere. The latter irregularity may require correction several hundred times in a minute, and a practised observer can introduce between one and two hundred per minute. The other difficulty—that the instrument is a visual one—Mr. Ritchey has obviated by the use of a delicately tinted yellow screen. This screen utilises the rays of light which are most freely transmitted by a large objective; since it is a well-known fact that while only a small percentage of the yellow rays are lost by transmission through a large and necessarily thick objective, a very large percentage of the blue rays are. Consequently the forty-inch visual

objective, thus used with a yellow screen, and plates sensitised to the yellow rays, is scarcely less rapid, if at all, in photographing stellar images, than an object-glass corrected for blue rays would be. In two hours it registers stars of approximately the seventeenth magnitude, which are at the visual limit of the instrument; and in five hours can register stars of a magnitude fainter. The yellow screen is formed from two thin and transparent plates, finely ground flat and highly polished. One of these plates, which are 8 by 10 inches, is flowed over with a collodion film of a delicate yellow tint, and when the film is dry, this is covered with Canada balsam, and the other plate bound on it as a cover glass by adhesive tape. When in use it is laid close upon the sensitive plate, nothing separating them but the tape. Mr. Ritchey has been most successful in photographing portions of the moon's surface, and close clusters of stars, and in Vol. VIII. of the Decennial Publications of the University of Chicago, several very fine specimens are given, notably one of the lunar crater Theophilus and its surroundings, which perhaps shows the detail on the moon's surface more clearly than any other photograph ever taken. In the photographs of the clusters Messier 13 and 15, the original negatives and transparencies from them show the star images separate and distinct, even at the very centre of the

THE DERBY CONVENTION :

SYNOPSIS OF THE WEEK'S PROCEEDINGS.

Monday, July 11.—Members of the Local Committee will act at the Mechanics' Institute to act as guides, and will arrange short morning and afternoon excursions as may be required. notice boards. At the Albert Hall of the Mechanics' Institute. Official reception by his Worship the Mayor (Councillor Corn Boam), the members of the Corporation, and other public bodies. eight o'clock, the President will deliver his inaugural address, at which the Exhibition of Photographic Apparatus, Pictures, etc., be on view. Musical promenade, refreshments, etc.

Tuesday, July 12.—Excursion to Dovedale—conveyances leave Strand, Derby, 9.0; arriving at Ashbourne, 10.45; leave Ashbourne, 11.45; luncheon at the Peveril Hotel, 1.0; conveyances leave "Peveril" for Ashbourne, 5.0; tea at Ashbourne, 6.0; leave Ashbourne, 7.0; arriving at Derby about 8.45. There will be no meeting on Tuesday evening.

Wednesday, July 13.—At the Mechanics' Institute.—The annual general meeting, election of Council, etc., 10.0; meeting of the Council, 11.0; the official Convention group will be taken by Mr

Dovedale: To be Visited by Members of the Convention on Tuesday, July 12.

cluster, but in the process reproductions given in the volume the smaller and nearer stars are merged together. With nebulae the yellow screen is not so successful since these are rich in their proportion of green rays, which do not come to the same focus as the yellow."

We have received from Messrs. Iliffe and Sons, Limited, 20, Tudor-street, E.C., a copy of "The Photographic Reference Book: a Cyclopædia of Photographic Information on all Practical Points." The work in a second edition of the volume bearing the same title published some time ago, and compiled by Messrs. W. A. Watts, M.A., and Henry Sturme, from the "Answers to Correspondents" columns of "Photography." The present edition is edited by Mr. J. McIntosh, and should form a useful handbook for the photographic worker.

The second edition of "Photography in Colours," by R. Child Bayley, F.R.P.S., is to hand, and in addition to dealing with the theoretical side of colour photography, gives in outline practical instructions for the working both of the Lippmann process and of the various three-colour methods, which were not included in the first edition. Every photographer interested in the process of colour photography will find much to interest him in this little volume, which is written in a very careful and lucid manner.

Barrow Keene. For time and place see notice boards. At Bri Hill, Belper.—Reception and garden party by the President Mrs. Strutt, 2.30. At the Royal Hotel.—Annual dinner and smother concert, 7.0.

Thursday, July 14.—Excursion to Hardwick.—Train leaves Midland Station, Derby, 10.5; arriving at Stretton, 10.53; leave Stretton coach, 11.0; arriving at Hardwick, 12.0; luncheon at the Hardwick Hotel, 1.0; leave Hardwick by coach for Stretton, 4.50; train leaves Stretton, 5.50; arriving at Derby, 6.25. At the Mechanics' Institute.—A paper, by Thomas R. Dallmeyer, Esq., F.R.A.S., on "The photography," followed by an exhibition of lantern slides by members of the Derby Photographic Society, 8.30.

Friday, July 15.—Excursion to Chatsworth and Haddon Hall. Train leaves Midland Station, Derby, 9.30; arriving at Rowsley, 10.20; leave Rowsley by coach for Chatsworth, 10.30; leave Chatsworth for Baslow, 1.30; luncheon at the Wheatheaf Hotel, Baslow, 2.0; leave Baslow for Haddon Hall, 3.0; leave Haddon, 5.15; leave Bakewell for Derby, 5.23; arriving at Derby, 6.30. A paper by H. Snowden Ward, Esq., F.R.P.S., on "Figures in Landscape," illustrated by lantern slides.

Saturday, July 16.—Various short excursions to places in and around Derby will be arranged as may be required. Members

by signifying their wishes to the Hon. Secretaries as early as possible, in order that particulars may be duly posted on the notice boards.

By the courtesy of the Platinotype Company, 22, Bloomsbury Street, New Oxford Street, London, we are enabled to give the appended reproduction of a souvenir postcard of the Newcastle Photographic Convention. The original portraits were printed from negatives exposed by the light of the Company's exceedingly effective y-magnesium portrait lamp, and the prints on the platinotype postcards were obtained by exposure to the same source of illumination. No doubt many of our readers, who are members of the Convention, will take the opportunity of securing a copy of the original postcard from the Platinotype Company. Reading from the top, and left to right, the names of the Conventioners are as follows:—

W. J. Croall.

K. Smith. The late Geo. Mason, C. H. Bothanley, J. Stuart,
Past Presdt. Past Presdt. Past Presdt.

NOTES UPON TIMING DEVELOPMENT.

[A paper read before the Birmingham Photographic Society.]

THE all important point in making a negative is to stop development at the right time to give the desired contrast in the print. Mr. Watkins has conclusively proved during the past ten years, and many of us have verified for ourselves that the time of the first appearance of the image, i.e., the time taken for the first sign of the subject to appear after the application of the developer, is a certain guide to the total duration of development under certain conditions; therefore, by taking advantage of this fact we can produce negatives possessing any desired contrast for printing in the various processes which require different ranges of gradation, and those possessing but little experience are enabled to develop their plates without fear of losing them through error in development. Further, a different make of plates may be used whose characteristics in development may vary considerably, the timing method settles this uncertainty; in the case of enlarged negative making one is very liable to misjudge the actual stage of development, first by reason of the amplification altering the general effect of the tones, secondly the difficulty experienced in examining a large plate exactly at the same distance from the developing light, and in the case of very large plates the almost impossibility to examine the stage of development by transmitted light at all; thirdly, the uncertainty existing with a large plate being more thickly coated than a small one.

All these and many other difficulties likely to cause the less experienced to "come a cropper" just when he is anxious to produce the best negative possible, are safely overcome by the adoption of development by time, and even the most experienced must find that the method is the only definite way to arrive at a given standard.

The "time of appearance" is carefully taken from the moment the developer is applied to the plate to the first sign of the high lights (this is easily obtained by the use of a watch with a large second hand, or, better, still, by the use of a Stanley's Dark-room Clock, the latter being a very useful accessory for other purposes photographic) and then that time is multiplied by a number called the factor, which gives the total length of development. Example: With a pyro. and soda developer (ammonia cannot be used) containing 2 grains of pyrogalllic acid, $\frac{1}{2}$ grain potassium bromide, water 1 oz., alkali q.s., a factor of 5 will give a negative of good contrast for P.O.P. printing, the first appearance takes, say 1 minute 10 seconds, then in 5 minutes 50 seconds from the pouring on of the developer the plate is ready for fixing. If a negative is required to give a good bright platinotype print use a multiplying factor of 6, but for Carbon printing a factor of 7 or 8 is necessary, especially with large negatives.

If the three solutions for pyro. and soda previously given by me are used then 20 minims of No. 1, 5 minims of No. 2, and 40 minims of No. 3 to each oz. of water, the correct proportion will be obtained.

The temperature will make a difference in the "time of appearance," but within reasonable limits will have no effect subsequently, the temp., however, must not be altered during the period of development, neither can the constituents of the developer without losing the benefit of the factorial method.

A pyro. developer containing to the oz of water 1 grain pyro. and $\frac{1}{2}$ grain bromide, a factor of 9 must replace 5, but should 4 grains of pyro. and 1 grain of bromide be taken then a factor of 4 would be correct.

If rodinal is used instead of pyro. and no bromide, a factor of 40 must be used, but if rodinal is used I recommend 25 minims of the stock rodinal to 1 oz. of water and $\frac{1}{2}$ grain of bromide, i.e., 5 minims of the 10 per cent. solution and a multiplying factor of 16.

With this timing method plenty of light may be used to make matters comfortable in the dark-room, there being no need to continuously expose the plate; as soon as the "first appearance" has been noted the dish should be covered over and very gently rocked for the remainder of the time. It will be found that a white porcelain dish gives the "first appearance" most successfully, coloured dishes are not good.

The method of timing development, whilst producing negatives of much more even quality, does not, of course, render mistakes impossible in the mixing of the developer nor in mistiming the "time of appearance," neither will it put right blunders of great extent in the exposure; the two matters of exposure and development are not so

closely allied as many suppose, however, space will not admit of discussing the treatment of under and over exposure at the present moment, but I have no doubt in my own mind that with slightly under and slightly over exposure, it will be found generally advantageous to stick to the time method—when a departure is made bear in mind that over-development of under-exposure and under-development of over-exposure must be rigorously avoided.—J. H. GEAR, F.R.P.S.

SOME NOVEL SUGGESTIONS FOR WINDOW DRESSING.

THE principal advertisement of a retail dealer is his shop window, and yet it is remarkable to notice how very frequently this most important part of the business is neglected. "Houghton's Monthly" gives some excellent suggestions which every retail dealer will, we think, find useful. To begin with, when the amateur is in doubt as to what camera to invest in, he usually makes a tour round to the various shops in his district and makes a close study of the windows. He may have read advertisements of some particular camera that has taken his fancy and he tries to find a shop that has one of the actual cameras in the window. He does not, as a rule, march boldly into the first shop he sees and ask if they have the camera in stock. He is too shy for that, for he does not like to come out without buying something, and if the camera is not all that the advertisement led him to believe, or what his fancy painted it, then he regrets his purchase and becomes dissatisfied. No, what he does is to go and study the camera through the plate glass, and get an impression of it before he goes inside to make a closer inspection. Now, as a rule dealers simply fill their windows with all kinds of stock, and if they have more than one model of any particular camera on show it is rather unusual. Consequently there is only one view of it to be obtained. What we would suggest is that, instead of the whole of the front of the window being filled up with a heterogeneous mass of accessories, a certain amount of space should be devoted to the display of one camera, or one or two cameras under varying conditions. Suppose we take a standard camera like the Sanderson for an example. One camera could be shown open, another closed, another with the bellows extended to the fullest, another with the wide angle movement in use, the front might be raised as far as it will go in another model, and dropped similarly in yet another example. If your stock is a large one you can show the half lens in use, have the back of the camera towards the window, show different sizes, types, accessories, and everything relating to it. Have a number of neat little cards written describing each camera or each movement, and above all have the price plainly marked, either on the showcards themselves or on a special card at the back of the display. Prints and enlargements taken from negatives made with the camera should always be liberally displayed, because the prospective buyer will go more by what has been done by others than by anything he is told that he can do. Of course all this takes time and trouble, but if you get a good result it will more than repay you for the little extra work. Again with box-form cameras there are a number of different ways of showing them, and, although they do not lend themselves to the display so well as a camera like the Sanderson, yet it is quite possible to make even a guinea camera seem the one thing desirable, provided that you go the right way to work. Specimens, and if possible striking specimens, have an enormous value in deciding the sale of a camera, and you cannot use them too freely. If you have any good local ones so much the better, only let them be good and technically perfect. One of your customers may be willing to lend you a negative, and if you think it is good enough, get one of the carbon or bromide manufacturers to make you an enlargement and display that. Your customer will bring his friends to see it and will become an unconscious advertising agent. We can always assist you if you want to make a special display, and can send you showcards and specimens of all descriptions. We shall have some more to say on this subject later on, but if you think that our remarks are worth adopting it is advisable to start now, because the holiday season has commenced, and you may be missing business.

THE B. J. JUBILEE.

THE following, from the pen of Dr. Moritz von Rohr, appears in the "Zeitschrift für Wissenschaftliche Photographie":—"On the 10th June this year the BRITISH JOURNAL OF PHOTOGRAPHY celebrated the fiftieth year of its existence. The following particulars concerning it may be of interest. The paper was founded as a monthly periodical under the name of the 'Liverpool Photographic Journal.' With the fourth volume a fortnightly issue was begun, and simultaneously the name of the paper became the 'Liverpool and Manchester Photographic Journal.' The larger size of to-day was adopted in 1859, on the issue of the sixth volume, and the name was then changed to the 'Photographic Journal,' but only to be altered in the following year to its present designation. With No. 217 of the 1st July, 1864, it became a weekly publication, and in October, 1892, a monthly supplement known as the 'Lantern Record,' was added. This was continued for ten years, when the supplement was suppressed and the weekly issue increased in size from 16 to 20 pages.

"The object of this paragraph is to express to our contemporary the hearty congratulations of the 'Zeitschrift für Wissenschaftliche Photographie.' Our German photographic periodicals cannot look back upon so many years of existence. If we except the 'Photographisches Archiv,' which has ceased to exist, the oldest papers are no doubt the 'Photographische Correspondenz' and the 'Photographische Mitteilungen.' But our congratulations do not relate to the age of the paper alone, but also to its important position.

The paper is not only large in size but contains valuable material for it not only gives information concerning all photographic processes, which appear in the domain of the English language, but also the more important which appear abroad. How large the circulation of the JOURNAL must be may be gathered from the fact that the 'Almanack,' which is also published at the end of each year by the same Editor, has reached a total of 25,000 copies published and sold. But this importance is not a growth of recent date. If I confine myself to the sphere of my own studies and occupation, that of optical questions relating to photography, I cannot value the importance of this paper too highly. Its direction by the first Editor, G. Shadbolt, was really excellent. To him the honour is due that he secured the co-operation of that eminent optician, Thomas Grubb, and at least induced that doyen of theoretical opticians, R. H. Bow, to take an interest in the work. We must also not forget to emphasise the fact that it was through the energetic action of the photographic Press that the wide-angle lens, free from distortion, evolved itself so successfully in the sixties in English-speaking countries. In this respect the action of this paper was of no small value. It was, in fact, through the lively exchange of opinions that the formation of so important a theorem as the Bow-Sutton law relating to rectilinearity became possible. Let us then express to the BRITISH JOURNAL OF PHOTOGRAPHY our best wishes in the words—

Vivat, crescat, floreat!"

Herr J. Gaedicke, the well-known and respected Editor of the "Photographisches Wochenblatt," also sends us his warm congratulations in the following terms:—"The oldest paper devoted to photography, which has continued to appear without interruption to the present day, could look back upon a life of fifty years on the 1st January last. We refer to the BRITISH JOURNAL OF PHOTOGRAPHY. It celebrated this Jubilee in a most worthy manner by the publication of a Jubilee Number on the 10th June. That this number has only just appeared, is due to the fact that the Editor, Mr. Thomas Bedding, has been suffering from a serious and long illness, to which he refers in the preface. The Jubilee Number is about three times as thick as usual and contains twenty-nine original articles by the more important contributors, together with their portraits. Besides this, the Editor contributes a history of the JOURNAL since its foundation and the portraits of the successive editors are also given. The paper was founded by the Liverpool Photographic Society, and was called the 'Liverpool Photographic Journal.' The first number appeared on Saturday, January 14, 1854. On the 1st January, 1859, the paper was called the 'Photographic Journal,' and on the 1st January, 1860 it was again renamed the 'British Journal of Photography,' which title it has retained till the present time. Among the editors of former

we find Sir William Crookes, then a young man. The late Traill Taylor conducted the paper admirably for the longest period, but with an interlude of seven years, which he spent in Africa. He died in 1895. The present Editor, Thomas Bedding, was Traill Taylor's assistant in 1891 in editing the paper, and after the death of the latter was appointed Editor-in-Chief. This respected paper, in the fifty years of its existence, represents a veritable history of photography, and it is the richest mine where evidence may be found to prove that many things offered now as novelties were known long ago. For instance, Forrest wrote on the 3rd February, 1888, that George Thomas photographed New Brighton Fort at a distance of three miles with a telescope, the actinic focal difference being $\frac{1}{4}$ in. We have the new telephotography. The paper has constantly maintained its prominent position of devotion to the whole field of photography, and has not taken any notice of the division of papers into amateur, professional, and pictorial. We congratulate our honourable colleague upon this Jubilee, and hope that in the next fifty years the importance of the paper will remain as high as hitherto."

The proprietors of the BRITISH JOURNAL OF PHOTOGRAPHY have recently published a Jubilee Number to mark the fiftieth year of its publication, though it has not always been known by the title it now bears. It was first started on January 14, 1854, as the 'Liverpool Photographic Journal,' and after going through many evolutionary stages, it assumed its permanent title of the BRITISH JOURNAL OF PHOTOGRAPHY on January 1, 1860, at which time it was in the able hands of Mr. Henry Greenwood, who retained control until his death in 1884. This Jubilee Number contains thirty special articles on the most popular and prominent phases of modern photography, written by competent specialists, besides an illustrated history of the journal since its foundation. In this history we find a list of the editors, among whom are many well-known men who have since made their names in the world of science. Among these we may mention James Alexander Forrest, 1854-1886; George Shadbolt, 1857-1864; George Pearson, Samuel Highley, Sir William Crookes, James Martin, John Traill Taylor, W. R. Bolton, and last but not least, Thomas Bedding, who at present fills the editorial chair in such an able manner. Such an event as the publication of this Jubilee Number is unique in the history of photography, and marks an important epoch in the science. We heartily congratulate our contemporary on the success it has so readily achieved, and trust that it will continue to flourish in the future as it has done in the past."—*The Chemical News.*

Photography fifty years ago appears to have been only possible for those with untiring energy and a long purse, we gather from the pages of the BRITISH JOURNAL OF PHOTOGRAPHY Jubilee Number, issued June 10. This is a special issue something like a beautiful album, though placed on sale at the usual figure (2d.), and any one is sufficiently interested in our hobby to read practically the history of photography, should certainly secure a copy of the same. Apart from the excellent value, one can gather from its pages the steady progress that has been made, understand how in the days of an outfit consisted of something like a small cart-load (should I escape work be desired), and the enormous amount of risk one had to undertake. All the old workers and best photographers who are now to tell the tale appear to have been more than pleased to contribute their mite for the benefit and encouragement of the present-day worker, and we feel certain that, after a careful perusal of the many odd pages, no one will dare to consider anything a trouble when they realise the difficulties that had to be contended with and surmounted not so long ago."—*The Hull News.*

The Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY will be found full of interest by all photographers, amateur and professional. As might be expected, the majority of the articles deal with the historical aspect of the art, and the lay mind, if it does not fully understand the technical terms and descriptions, is at least enabled to grasp the fact of the great difference that exists between the methods of the present day and those of the time when the first number of this well-known and esteemed journal was issued. To those practising photography at the present time, accustomed to all the easy devices so lavishly supplied, the difficulties which beset the early students will appear insuperable. However, they have here the personal evidence of some of those forerunners that convinces them,

for the number includes contributions from photographic experts, who have been identified with the journal for thirty, and even forty years."—*Sheffield Daily Telegraph.*

"We owe an apology to the BRITISH JOURNAL OF PHOTOGRAPHY for not previously offering our congratulations on its Jubilee Number; but we see that we are not alone in being unable, from press of matter, to insert contributions with the promptitude which is desirable. It is not too late to call attention to the admirable history that this number affords of the development of photography and of the progress of the JOURNAL; whilst the biographical details relating to successive editors and contributors are of very great interest. We are glad to see a notice to the effect that 'advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.' Advertising agents, in their anxiety to 'do business,' are unconsciously doing their best to depreciate the value of legitimate advertisement, and to injure the reputation of those journals which do not strictly maintain the distinction between the advertising and the editorial departments."—*The Gardener's Chronicle.*

"Accept my heartiest congratulations on the Jubilee Number of the dear old B.J. It is in many ways the most interesting number I have seen since I first began to scan its pages twenty years ago. May we all live to enjoy the Centenary issue.—Yours cordially, JOHN A. TENNANT, Editor, 'The Photo-Miniature' (New York)."

A NEW SUGGESTION FOR HOLIDAY PARTIES.

At first sight a holiday spent amidst scenes of work appears somewhat unromantic. Coalmines and factories, steelworks and quarries, are not considered so picturesque as the cloud-swept mountain range, or the eternal stillness of the placid pool. An industrial centre is a strange place to one who has not been brought up in its midst. It is often said that the manufacturing districts are horrid places. But is this true? They have a beauty of their own which is soon revealed if a short stay is made in one of them. There is a wild grandeur in the flame that shoots up from the blasting furnace. The clang of hammer on steel at the foundry is but labour's melody. Who could stand at the pit-head and watch the tons of coal ceaselessly rise from the darkness of the pit without being impressed? To see and know how such things are done—these are some of the lessons that industrial England has to teach. A solitary traveller working by himself suffers from many disadvantages. He can often see but the outskirts of many places that he would wish to enter. The information that he derives may not be accurate. Much valuable time is often lost in not knowing the country well, and also in not knowing which are the likely farms to apply to for permits in order to see their works in operation. On the other hand, if a party were organised, pioneered by an efficient guide, with letters of introduction to the heads of the commercial centre from which they wish to radiate, the chances of a successful educational trip would be greatly enhanced. Let us suppose a party of young men desirous of seeing England at work. How easy it would be if some influential man would take up the idea, and by obtaining the necessary letters of introduction, not only would the gates to many interesting sights be open, but efficient men to explain the marvels that could be seen within would also be obtained. In the same way that parties are pioneered through Italy, Switzerland, or even places like Oxford at home, could a party of men and women be shown round some of the workshops of England. By living amongst the people, becoming associated with their institutions and their modes of life—different in so many respects from those followed in other parts of the country—and by watching the mighty thread of England's industry being woven before their eyes, surely that would constitute a holiday as instructive as it would be interesting and useful.—Mr. F. A. Hunt, in "The World's Work" for July.

Patent News.

The following applications for Patents were made between June 6 and June 25, 1904:—

- Enlarging Apparatus.—No. 12,734. "Improvements in photographic enlarging or reducing apparatus." Henry Rex Cook.
- Raising Ferrottype Plate Paper.—No. 12,834. "Method of clipping and raising ferrottype plate paper and other photographs." Joseph Richardson.
- Cameras.—No. 12,883. "Improvements in or connected with photographic cameras." John Weston Brooke.
- Stand Attachment.—No. 12,923. "An attachment to a photographic camera stand for the purpose of taking stereoscopic views." Alfred James Giddings.
- Cameras.—No. 13,005. "Improvements in photographic cameras." Arthur Lewis Adams.
- Photographing Coloured Objects in Monochrome.—No. 13,179. "An improved method of photographing coloured objects in monochrome." The Gem Dry Plate Company, Limited, and Thomas Thorne Baker.
- Shutters.—No. 13,183. "Improvements in 'focal plane' shutters for cameras." George Jones, trading as Talbot and Eamer.
- Mounting Photographs.—No. 13,472. "A new or improved process for mounting photographs and the like." Complete specification. Friedrich Wilhelm Gustav Chelius.
- Masks.—No. 13,774. "Improvements relating to gauges and masks for use in photographic printing." Complete specification. Frederick Charles White.
- Postcard Printing Frames.—No. 13,893. "Improvements in and connected with frames for printing picture postcards and the like from a photographic negative." John McInnes.
- Film Developing Apparatus.—No. 14,069. "Improvements in apparatus for developing photographic films." Complete specification. Jonathan Millard Brainerd.
- Printing Frame.—No. 14,110. "Improved photographic printing frame." Robert Arthur Montagu Boyce.
- Magazine Attachments.—No. 14,329. "An improvement in magazine attachments or charging packets for photographic cameras." Newton Livingstone Scott.

A NEW "ENSIGN" FILM COMPETITION.

DURING the months of July, August, September, and October, 1904, a monthly competition will be held in connection with the "Ensign" Film. Twenty pounds every month will be distributed among those who send in the largest number of the labels that are pasted on the bottom of the "Ensign" Film boxes. There are no conditions or rules to be observed, and no coupons have to be obtained. All that has to be done is to cut off the bottom of the box in which this film is packed, with the label containing particulars of the batch number, date, etc., and send as many as possible to Austin Edwards, The Film Factory, Warwick, before the end of the month in which you intend to compete. Mark the package "Ensign" Competition. Enclose name and address and remember that two six-exposure spool labels will have the same value as one twelve-exposure label. In the case of the smallest films, which are packed four in a box, the label of one box will count as four spools. The prizes will be awarded as follows:—To the person sending the largest number of labels in any one month, £10; to the person sending the next largest number in any one month, £5.

There are also five other prizes of £1 each to those who come nearest to the winning collections, making twenty pounds in all to be distributed each month. All sizes rank equally in this competition, and there is no distinction made between users of different sized spools. Competitors may ask their friends to collect labels for them. Do not wait until the last month when the entries will be heavier; the earlier labels are sent in the better chance there is of winning a prize. Twenty labels may win the first prize, and this will work out at ten shillings a label, so that you see the offer is one that is worth consideration.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July	Name of Society.	Subject.
11	Southampton Camera Club	<i>Imogen Sulphite</i> . Demonstrated. A. E. Henley.
12	Nelson Photographic Society...	Members' Print Evening.
13	North Middlesex Photo. Soc.	<i>Orthochromatic Photography</i> . Arthur Payne.
13	Everton Camera Club	Competition.
14	Watford Camera Club	Competition—"Architecture."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 30, 1904.—Annual general meeting. Mr. A. Haddon in the chair.

HONORARY SECRETARY AND TREASURER'S REPORT

In presenting to you my first report I must claim youth and inexperience as an excuse for any failing you may detect in the account of my stewardship, as against which I lay at the members' doors the my eyes, heinous crimes of not attending as frequently as could be wished, and also a strange aversion to paying subscriptions. However, figures and facts are hard nuts to crack, and, having charged you with these failings, I now appear for the defendants, so to speak, and prove that you are no worse in both respects than you have been in years gone by; in fact, you are rather improved.

Membership is the great factor in a society's vitality, and although the grand total of members has been somewhat reduced, it is only because a few names of non-paying, non-attending members have been struck off by the committee; these gentlemen are quite useless to the society. If they paid and did not attend, or attended and did not, they would be useful, but doing neither they are a luxury we must dispense with. We have elected 11 new members this year, of whom have resigned, making a net increase of 9. We have struck off 8 bad eggs and 3 have resigned, making a decrease on the roll of two, and our membership is now exactly 100. There have been 50 meetings, as usual, and the average attendance is 21, which I think is good. The smallest was 13, the largest 50. We have had what I may term some notable papers this year, and I think would be invidious to name any in particular, because I do not think that any paper can justly be described as mediocre. Some of the papers have kept the Press in free copy for weeks. I refer especially to the one on the metrical system, by Mr. Gotz and the psychic effort of Blackwell. We have had 22 open nights, for which the summer months have been responsible, it not being fair to ask a lecturer to come down and not to present him with an audience. We have had 7 lectures pure and simple, 17 papers of technical interest, 2 technical demonstrations, and two nights have been taken up by business of the society. This past year is notable as having been the first year of the Henderson Award, which has lain dormant since it was given to the association by Mr. Henderson. I fear the next awarding may lead to much discussion. We have had so many good original papers. Mr. T. Thorne Baker was the recipient this year. The Anonymous Award was given to, and deserved by, Mr. Fowler, a remarkably useful gentleman, who always seems to have a paper ready, and is handy in taking the secretary's place when the gentleman feels lazy.

Our thanks are due to Mr. Harvey Piper for one of our large attendance, and to departed friends for the largest meeting of the year, the "ghosts' evening" before referred to bringing up fifty members and friends who were very much alive. These meetings were only surpassed by the supper (55), which I have heard was excellent; I did not get myself. But we must express our appreciation of Mr. Grant's many friends, who did so much to cheer us up, and our thanks to Mr. Grant for bringing them. This occasion was marked by the return of an old member, Mr. E. J. Wall, to photographic society life after months' illness.

I must, in referring to the library, which has been enriched by many newly-bound volumes of the weekly and monthly Press, express

pathy with Mr. Marshall. A word for our energetic recorder, who has been very busy in sending out and writing splendid reports of meetings, and I have done.

Expenditure this year has increased by £3 7s. 11d., due to votes for lantern, amounting to £2 15s. 9d., and lantern stand, 12s., both additions to assets of the associations. Our income has fallen £1 15s., no less a sum than £12 15s. being due to the association's subscriptions of 1903-4. The gentlemen who are represented must have the liability of the large item of 7d. per head ago laid at their doors, the normal amount being 4d., which should be ample. Rent is low, being 2s. 4d. per head. Subscriptions to the Royal costs 3d. per head, a charge which will assist in the coming year, as 1d. per copy is to be charged for the Book. Printing and stationery is a heavy item, being nearly equal to the other.

Following officers were elected:—Trustees: Messrs. A. Haddon, E. Freshwater. Committee: Messrs. S. H. Fry, Hart, T. K. R. Beckett, Teape, P. R. Salmon, H. C. Rapson, and A. Beddard. Hon. Lanternist: Mr. Wright. Hon. Recorder: W. T. On. Librarian: Mr. W. J. Marshall. Affiliation Delegates: Mr. Furley Lewis and H. C. Rapson. Hon. Secretary and Treasurer: Mr. R. J. Kindon.

New Books.

"Dictionnaire de Chimie Photographique." Part V. Gauthier-Villars, 55, Quai des Grands Augustins, Paris.

We have recently received the fifth section of this work, by Messrs. Ad. Braun fils, which is intended as a chemical book of reference for amateur and professional photographers. This part includes sections extending alphabetically from "Emulsion" to "Gomme," "Ethers," "Salts of Iron," and "Gelatin" are dealt with, it will be specially interesting.

"Lehrbuch der Photographie." Vol. 49. Optik für Photographen. F. Stolze. Wilhelm Knapp, Halle a/S.

This volume, which has been specially written as a text-book for men in Technical Photographic Schools, deals with optics in relation to photography. The nature of light, its refraction, the properties of prisms and photographic lenses are dealt with in a very simple manner. The lenses of the leading opticians are also brought under review. The book should give the photographer an intelligent view of the optical part of his outfit, and we warmly recommend it.

"Directory of Chemists and Druggists." 711 pp. Price 20s. London: Published by Kelly's Directories, Ltd., 182, 183, 184, Abchurch Lane, London, W.C.

There can be no doubt as to the usefulness of this work to those connected with the chemical trades. In the pages of the book will be found the names of over 56,000 persons, being an increase, as compared with the last edition of the work, of about 10,000. These include the manufacturers of almost every chemical of importance to have a separate heading, as well as a considerable number of trades that have not previously appeared. The scientific branches are also included, such as the analytical and organic chemists, members of the Pharmaceutical Society, etc., and the scientific researches are constantly developing important results. The contents are arranged admirably for reference. Places in England, Scotland, Ireland, and Wales, with the names of persons engaged in business in each, arranged alphabetically in counties, and by a cross-reference list of trades, arranged alphabetically.

Hon. Sec. of the North Middlesex Photographic Society writes that the outing arranged for July 16 has been altered to Rowley Green.

News and Notes.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on the 4th instant, the Duke of Northumberland, K.G., president, in the chair. Viscountess Gort, Mr. M. H. Spielmann, and Mr. W. R. W. Sullivan were elected members.

An interesting series of pictures illustrating the stirring times experienced by the British Expedition to Tibet at the present moment has been sent in to Kodak, Limited, by Lieutenant F. M. Bailey, of the Pathan Mounted Infantry. They were taken with the No. 3A folding pocket Kodak on the N.C. film, and, besides being excellent as pictures, they are important as records, and doubtless reproductions of them will find their way into the leading illustrated weeklies.

The National Trust for Places of Historic Interest or Natural Beauty have an option to purchase Aira Force, the romantic gorge of the Aira, and Gowbarrow Fell, on Ullswater. This beauty-spot is familiar to all artists and users of the camera who have been fortunate enough to visit the locality. The land which it is proposed to acquire comprises over 700 acres, and includes a mile of the shore of the lake, above which towers the summit of the fell nearly 1,600 ft. above sea level. The actual purchase-money required is £12,000, but a balance will be needed to meet expenses, and it is desirable, if possible, to secure also some adjoining land, which is offered on advantageous terms.

We have received two useful little guide-books that should prove of much use to the holiday-maker who takes his camera with him. One is entitled "Holidays in Eastern Counties," and prominence has been given to some less-known districts in East Anglia which will well repay a visit. The other deals with a series of tours in less-known districts of Holland, North Germany, the side valleys of the Rhine, the Tyrol, the Belgian Ardennes, and Scandinavia, easily and inexpensively reached by the Great Eastern Railway Company's routes via Harwich and the Hook of Holland and Antwerp. Both these booklets are well illustrated, and may be obtained on application to 30, Fleet Street, London, E.C.

RECORD and Survey Photography receives due recognition in the schedule of the Newbury Photographic Exhibition, to be held in the autumn, one class being devoted to work of this nature; and as the county of Berks is particularly rich in antiquities and historical associations an interesting collection should result. It was at Newbury that two of the fiercest battles of the Civil War were fought, and the old houses adjoining the Bath Road afford interesting reminiscences of the days of coaches and worthy subjects for the camera. In this competition the Mayor of Newbury, who is a keen antiquarian, has offered prizes to the value of three and a half guineas on condition that the prize-winners give copies of the successful prints to the local museum.

By the death of Mr. G. F. Watts, R.A., England not only loses an artist worthy to rank with the great masters of the past, but also one of the most potent spiritual forces of the nineteenth century. His passing severs another of the links which connect our age with that of Carlyle and Scott, Thackeray and Dickens, Browning and Tennyson, Ruskin and Turner, Martineau and Gladstone. As an artist Watts ranks with the great masters by reason of his work being marked by three attributes rarely combined. In the first place, there is always a great conception; he held that a picture must have a message, that lacking this, in his own words, it was "like a face without eyes." In the second place, he was a perfect draughtsman; in the third, a no less admirable manipulator of colour. As far back as 1857 Ruskin wrote: "We have, as far as I know, at present amongst us only one painter, G. F. Watts, who is capable of design in colour on a large scale." His ideal of portraiture has been well described "as the intimate study of a man in the mood of his vocation," and his portraits of Tennyson, Gladstone, Carlyle, Joachim, Rossetti, and Cardinal Manning witness to his idealizing of the subject.

THE NATIONAL PORTRAIT GALLERY.—The 47th annual report of the trustees of the National Portrait Gallery has been issued as a Parliamentary paper. The report states that Mr. Watts's portraits of Lord

Salisbury and Mr. Lecky, painted in 1884 and 1878 respectively, have been accepted as part of Mr. Watt's original gift to the nation, the usual rule as to the expiration of ten years from the date of death being suspended, as on former occasions. This rule was also suspended in the case of the terra-cotta bust of Mr. Lecky and the marble bust of Mr. Herbert Spencer, both modelled by Sir Edgar Boehm, R.A., and of the portrait of Herbert Spencer, painted in 1872 by John Bagnold Burgess, R.A. The total of visitors from January 1 to December 31, 1903, is stated to have been made up as follows:—Visitors admitted free of charge, 120,303; visitors admitted on payment of 6d., 9,016; visitors admitted on Sunday afternoons, 11,368; total number of visitors admitted in 1903, 140,687. The report further gives particulars regarding other portraits acquired by purchase or gift during the year—the total number of additions to the collection being 28—of loans made to other collections, and of copies of portraits made by students.

A DIPLOMA, as officer of the French Academy has been awarded to J. C. Strauss, a St. Louis photographer, whose studio is on Franklin Avenue, near Grand Avenue, an honour which is conferred by the Ministry of Public Instruction and Fine Arts on artists deemed worthy of special distinction. The diploma was awarded by Paul Lascombes, a delegate of the Ministry, who, with Felix Lamy, secretary of the French Commission to the World's Fair; Marcel Hortiloup, Commissioner of Fine Arts at the Exposition; Paul Delestre, who holds a similar position; and Charles Gerschel, a photographer of Paris, went to the Strauss studio at three o'clock yesterday afternoon. They found Mr. Strauss, who did not know of the honour about to be conferred upon him, at work in his shirt sleeves. M. Lamy, secretary of the French Commission, impressed with the work of Mr. Strauss on exhibition in the Palace of Fine Arts, several weeks ago suggested to M. Lascombes that he be appointed an Officer of the Academy, although this honour is conferred upon few foreigners. M. Lascombes readily acquiesced in the plan and cabled to J. Chaumie, French Minister of Public Instruction and Fine Arts, asking that the violet ribbon which is the insignia of the honour, be awarded to the St. Louis artist.—“St. Louis Republic.”

Commercial & Legal Intelligence

RE Blyton Wainman Powls and Alfred Arthur May, trading in partnership as Powls and May, photographers, of 301, Summer Lane, the former residing at Birchfield Road, Aston, and the latter at 17, Crompton Road, Handsworth. The above named debtors appeared for their public examination at the Birmingham Bankruptcy Court on June 23 before the Registrar. The statement of affairs filed by the debtors showed liabilities amounting to £857 8s. 11d., deficiency £772. In reply to the Official Receiver, Powls said he was a grocer's manager until 1887, when he went into partnership as a photographer with May, who had been a grocer's assistant. Their capital amounted to £100. The business was very successful at first, being conducted largely on the club system, with agents among the factory girls. In November, 1902, the greater part of the premises was destroyed by fire. The damage amounted to £710, of which they received £410 from an insurance company. Owing to declining trade the firm was unable to recover the loss through fire. They borrowed money, and sold their furniture, but as they were trading at a loss things went from bad to worse till they had to suspend payment. Asked why they continued to draw £4 each out of the business for household expenses, Powls said he set up a big establishment when he thought he could afford it, and found it difficult to reduce expenses. He was now earning nothing. May said that he was now acting as manager for Mr. Bennett, who was carrying on the business. He could add nothing to what his partner had said in explanation of the heavy drawings.

ART COPYRIGHT.—HANFSTAENGL v. MACFADDEN.—This was an action which had been remitted from the High Court, and in which the plaintiff, Mr. Franz Hanfstaengl, a fine art publisher, claimed damages from the defendants, Mr. B. Macfadden and Mr. William Henry Gale, for the infringement of the copyright of a picture called “The Sirens,” by the German artist, Paul Thumann. Mr. Montague Lush, K.C., who (with Mr. Morton Smith) appeared for the plaintiff,

said Mr. Macfadden was an American gentleman living in America and carrying on apparently a very large business in copying pictures and sending them over to this country for sale. He also published such pictures in magazines called “Beauty and Health,” “Physical Development” under circumstances which, counsel contended, only tended to debase the picture and destroy the value of the copyright. Mr. Gale was Mr. Macfadden's manager in England. There were also some hundreds of copies of the picture in a portfolio, entitled “The Human Form Divine.” Mr. Ludwig Schubert, manager to the plaintiff at 16, Pall Mall East, stated that Mr. Hanfstaengl had carried on business in London for fifty years. “The Sirens” had a considerable sale in its reproduced form, prices ranging from one guinea to one shilling. They had had considerable trouble with infringements, especially from America. In cross-examination by Mr. Lewis Thomas, who represented the defendants, the witness admitted that there was no register in England showing that the picture was copyright or that it was registered in America. He also admitted that defendants, on learning that the picture was copyright, at once stopped the sale of the magazines, portfolios, and offered to pay any reasonable amount of damages. Mr. Algernon Graves, fine art publisher, stated that in his opinion the piracy tended considerably to damage the value of the copyright of “The Sirens.” In cross-examination, he admitted that the London house did not stock the picture. The jury awarded the plaintiff the sum of £100 as penalties and damages. Judgment entered accordingly, with costs.

SHALL LONDON HAVE A GREAT INTERNATIONAL EXHIBITION?

THIS is a question raised by the “Magazine of Commerce” a month ago. The current number of that magazine now gives the interesting result of a referendum on the subject among the representative group of British manufacturers. It appears that 100 firms consulted, 36 are for the exhibition, 32 are against, and 32 are neutral, while 17 are considering the subject. Mr. G. Balfour, the President of the Board of Trade, endorses the proposition provided he can be assured that he will have the support of the commercial world. Hence the referendum instituted by the “Magazine of Commerce.” It is interesting to note that some firms object to an exhibition. Their decision is emphatic and final. One or two of the objectors raise the familiar argument that in a Trade country a Great International Exhibition merely gives foreign manufacturers an opportunity of copying our methods, and our goods from our own home markets, and from the few foreign markets over which we still have an ascendancy. The argument, in fact, of these objectors is that a great exhibition is good for a Protectionist country, but bad for a free-import country. We have no standard of comparison in reasoning with this argument, as we are practically the only free-import country of the world. It is none the less apparent that there are many manufacturers who would be deterred from supporting an exhibition on these grounds. Considering the fact that foreign nations would be sure to take advantage extensively in a Great United Kingdom Exhibition, the English manufacturer would have before him very numerous examples of his imitation, and from which he would derive valuable suggestions. In other words, the advantages of the exhibition, from the public standpoint, will outweigh its disadvantages. Many people seem to think that they can do more good for themselves by hiding their light under a bushel. Publicity is bound, sooner or later, to take any good article; and manufacturers should make public their servant rather than their master. The suggestion is that the exhibition should be chiefly, if not entirely, intercolonial in character. By all means let the colonies play the most important part in the exhibition—they may safely be trusted to value their own interests in that respect—but the colonial character of the exhibition should not deprive it of the great value and importance attached to a cosmopolitan gathering. If the exhibition were confined to the colonies, it could not attain the high rank of international exhibitions held in other countries. It would be regarded by the world as a domestic matter of our own, and the influx of visitors would decrease accordingly. To do the thing the suggested exhibition should be both intercolonial and international. There is no reason why the two features should not be harmonised, unless we are to indulge in the chimerical hope that the British Empire can be run successfully as an isolated unit of world of gregarious nations.

FORTHCOMING EXHIBITIONS.

October.—Glasgow Photographic Exhibition. Secretary, Art and Museum, Kelvingrove, Glasgow.
 14 to September 30.—Vienna Photographic Society. Secretary, Karmelitergasse 7, Vienna 11.
 August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.
 August 16-20.—Royal Cornwall Polytechnic Society Photographic Exhibition. Secretary, Edward Kitto, The Observatory, Falmouth.
 September 16 to November 5.—Photographic Salon, Dudley Gallery, 11, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.
 September 20-28.—Newbury Photographic Society. Hon. Secretary, Forster, Guildhall Club, Newbury.
 September 22 to October 29.—Royal Photographic Society's Forty-first Exhibition, New Gallery, Regent Street, London. Secretary, W. Bartlett, 66, Russell Square, London, W.C.
 October 1-30.—Berlin International Photographic Exposition. M. Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.
 October 19-22.—Rotherham Photographic Society. Hon. sec., H. C. Ringway, Tooker Road, Rotherham.
 November, 1904.—Ilford and District Photographic Society. Hon. W. N. Beal, 155, Thorold Road, Ilford.
 November 3.—Frome M.I. Photographic Society. Hon. Secretary, Mitchell, 3, Willow Vale, Frome.
 November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., Dunlop, Myrtlebank, Motherwell.
 November 9.—Hackney Photographic Society. Hon. Secretary, Mr Selfe, 70, Paragon Road, Hackney, London, N.E.
 November 15-16.—Ipswich Camera Club. Hon. Secretary, R. H. 37, Henley Road, Ipswich.
 November 21-26.—Sheffield Photographic Society. Joint Secretaries, Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
 November 23-26.—Hove Camera Club. Hon. Secretary, A. R. 55, The Drive, Hove.
 November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., Simmers, Aberdeen House, Ramsgate.
 November 2-8.—Southsea Photographic Society. Hon. Secretary, Lawton, 20, Clarence Square, Gosport.
 November 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, 101st Street, New York.
 November 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
 November 13-20.—Southampton Camera Club. Hon. Secretary, S. G. 37, Oakdene, Highfield, Southampton.
 November 28-31.—Wishaw Photographic Association. Hon. Sec.—Robert Telfer, 138, Glasgow Road, Wishaw.
 December 14-28, 1905.—The Scottish National Salon. Hon. Secretary, J. Frame, 28, Bank Street, Hillhead, Glasgow.
 December 21 to March 7, 1905.—Glasgow Southern Photographic Exhibition. Hon. Secretary, W. A. Frame, 23, Bank Street, Hill-Glasgow.
 December 1905.—Northern Photographic Exhibition. Secretary, F. G. 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
 October 16.—Luna paper. £240 cash prizes for prints on Luna paper. Messrs. Allegre and Co., 59a, New Oxford Street, London, W.C.
 November 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.
 November 31.—Coxin. 68 prizes for users of Coxin. Judging twelve prizes. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
 November 1.—The "Graphic." £50 in cash prizes. Manager, Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.
 November 31.—Barnet. Nineteen classes. Prizes valued at £500

for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE KODAK COMPETITION.

To the Editors.

Gentlemen,—June 30, the closing date of the Grand Kodak £1,000 Amateur Competition, brought in sacks full of entries, which now number many thousands. The clerical work attaching to such a competition as this is considerable, and it will be perhaps two or three weeks before the result can be made known. As a whole the exhibits are up to a very high standard, and to adjudge them will be no sinecure.—Yours faithfully,
 KODAK, LIMITED.
 41-43, Clerkenwell Road, London, E.C., July 1.

THE list of applications for space in the forthcoming Loan Exhibition of Process Engraving in Monochrome and Colour, to be held at the Victoria and Albert Museum in October, will, it is understood, be closed very shortly. The exhibition will include photo-lithographic and collotype processes, and a complete historical series of examples, showing the gradual development and uses of these and the others represented is being arranged.

PHOTOGRAPHS and FRAUD.—In photographs of the swindling London Penny Omnibus Association's premises that were issued to the public the same horses were placed in various stalls in the stables, and a very pretty picture was made by bringing in a borrowed coach and four. Some stables at Walham Green were described as the "head depot," a room at Fulham Road became the "main traffic office," the "stores and granaries" were said to be situated at Fulham, Hammersmith, and Westminster, and there was an alleged "grazing" farm at Ockenden. When the association went into bankruptcy, claims from the public to the extent of £18,000 were made, but the creditors only received one penny in the pound. Sentence of five months' imprisonment was passed at Clerkenwell yesterday on Arthur Bartlett, a joint manager of the association, who was charged with conspiracy with Knowles, the secretary (now "wanted" on a warrant), to defraud the public.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c. One Year ...
Half Year	5	5	13s.
Quarter Year	2	9	

It may also be obtained from all Booksellers, Photographic Dealers, and Railway Bookstalls.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Samuel Nixon, of Glenvista, Creggan, Londonderry, Ireland. *Photograph, Showing Mrs. Kerrigans, of Leenane, co. Galway, Ireland, standing by her Spinning Wheel, also the Chair upon which the King sat, and the Cabin (or House) in which the King and Queen Visited Mrs. Kerrigans in the year 1901.*

H. Bennett, Church Lane, Goosnargh, near Preston. *Photograph of Block of Buildings with Landscape; the Anneze portion of the County Asylum, Whittingham, near Preston.*

Louis G. Carpenter, 88, High Street, Ramsgate. *Photograph of H.R.H. Princess Louise, the Duke of Argyll, the Mayor of Ramsgate and Officials on Balcony of Royal Victoria Pavilion, Ramsgate.*

Chas. Foster, Photographer, Promenade, Port St. Mary, Isle of Man. *Photograph of the Crew of the Fishing Vessel "Harvest Home," Lying and Carting Nets.*

BACKGROUND.—We do not know the gentleman's present address. Better consult the advertisement columns of the JOURNAL, as it is quite against our rule to recommend any particular maker's goods.

UNEXECUTED ORDER.—JACKSON says: "Several weeks ago I received this list of a paper. I sent stamps for sample. Some weeks elapsed, when I wrote reminding them I had not received it. I then got a post-card saying they could not get raw paper, but would do so in a few days. I have heard nothing since. Do you know anything about it?" In reply: We know nothing about it whatever. Better write to the firm again and remind them of the matter.

LENS FOR ENLARGING.—S. CHAMBERLAIN says: "(1) I have just come across an old camera made by J. F. Shew, 89, Newman Street, Oxford Street. But the lens is an Alexis Millet, of Paris, No. 1615. It is 3in. in diameter, and is a double achromatic portrait lens. Can you tell if this is a first-class lens? (2) The approximate worth of it; and (3) to what size it will enlarge? If not, can you, please, tell me the way to find out the above questions?" In reply: (1) We could give no opinion unless we tested the lens. (2) Better get the value from Messrs. Shew. (3) To any size, provided it will cover the size of the negative to be enlarged.

TONING TROUBLE.—"P. O. P." asks: "Can you tell me the cause of the trouble I have with my sulphocyanide toning bath? When used a second time it turns prints a faint yellow colour, when first put in, and works slowly; viz., prints get a pink tint on the edge. I have reason to know the bath has enough gold in it, yet the trouble seems to come from lack of gold. I am careful to have everything used perfectly clean, but cannot get over this trouble. It seems to come only in hot weather." In reply: It is pretty evident that the bath is deficient in gold, notwithstanding your statement to the contrary. Add more gold and see the effect.

CARBON LANTERN SLIDES.—"LANTERNIST" says: "I should be greatly obliged if you would advise me on the following points:—(1) In the 'B.J.P.' for October 30, 1903, p. 867, 'Caledonian' states that no coating of the glass is necessary in making carbon lantern slides, but on p. 923 of November 20 this is contradicted, which is correct? (2) Are lantern slides made by the carbon process as good as the ordinary slides? (3) What is a good formula for white ink, to be used with an ordinary pen, for writing titles on dark mounts?" In reply: (1) We should

certainly advise the use of a substratum on the glass. (2) This is very much a matter of opinion. However, the carbon process yields excellent slides. (3) Chinese white, as sold in tubes artists' colourmen, mixed with thin gum water.

SPOTS ON PRINTS.—"J. B." says: "I have used with great satisfaction the chromic acid treatment for bromides from too contrasty negatives, but on trying it with gaslight paper (Velox) have been troubled with black spots on the print so treated. I enclose print which was exposed entire, then divided, one half bathed in chromic acid solution, and the two portions then developed at the same time and in the same dish. I will observe that the print developed in the ordinary way was free from the markings. I shall be much obliged if you suggest any preventative of or cure for the 'spots.'" In reply: Evidently there were some particles of matter in chromic acid bath that had a reducing action where they came in contact with the print. The other half of the picture being evidence of slovenly work. We should suggest more care in the manipulations.

SPOILT COLLODION.—"B. C." says: "(1) Some time ago I had misfortune to spoil a considerable quantity of enamel collodion by getting some water accidentally mixed with it. A quantity of water was only small in proportion, but sufficient to render the collodion useless in its present state. When poured on the glass in the usual manner it does not 'set' as it should but turns milky and spongy. Is there any way of rescuing collodion, or will it have to be thrown away? (2) I shall be obliged if you can give me a recipe for making celluloid varnish for negatives." In reply: (1) Pour the collodion into a dish, and allow it to become thoroughly dry, and then dissolve in equal parts of ether and alcohol. Unless you use a large quantity, it will scarcely be worth the trouble. (2) The simplest way is to clean spoilt celluloid films and then dissolve in a mixture of equal parts of amyl-acetate and methylal spirit.

VELOCITY OF BULLET.—E. M. PARS writes: "I have been interested by the appearance in various photographic weeklies of a photograph of a rifle bullet taken at one-millionth part of a second. I shall be pleased to hear how the velocity of this bullet has been arrived at. The BRITISH JOURNAL OF PHOTOGRAPHY, its Jubilee Number, gives the velocity as 20,000 ft. per second, but a week later it is given as 3,000. The 'Photographic News' of June 10 says 30,000 per second, and a paper which I cannot lay my hands on at the moment, if my memory serves me correctly, gives it as 40,000 ft. per second. I think I am right in stating that the ascertained velocity of any rifle bullet very rarely exceeds 2,000 ft. per second, varying a little according to the make of the rifle and the amount of powder used." In reply: We cannot say how the velocity of the bullet was arrived at. Perhaps, if you write to the makers of the plate upon which the photograph was taken, they will give you the information you desire. You see, the illustration is simply an advertisement for a particular make of plate.

STUDIO QUERY.—"STUDIO" asks: "Will you please advise me regarding the following? I have small studio, sitters' end facing north, 15 ft. 8, roof and one side glazed clear glass. I have 4 ft. block sitters' end, which I see you advise. I have no knowledge of studio work, but in so short a studio sitter will be very close to the background, say 1 ft., and it seems to me when blinds are fitted I shall have no control over light on sitter. Will you kindly inform me if I shall find this so in practice? If 4 ft. is too much to block in so short a studio? 2. What colour blinds do you advise? 3. What can I stipple glass with on roof? 4. How can I fix blinds on roof? 5. Should blinds on side light work from top to bottom, or in sections, top centre, and bottom to centre, overlapping one another?" In reply: 1. The studio is certainly very small, but there is reason why the sitter should be so close to the background. 1 ft. Then 4 ft. will not be too much to be blocked. Medium blue or pale green. 3. Starch paste mixed with little whiting is as good as anything. 4. The ordinary brackles such as are generally used for window blinds. 5. For the side, curtains running on rods will answer well.

EX CATHEDRA.

The Photographic Convention. The nineteenth annual meeting of the Photographic Convention of the United Kingdom was opened at Derby on Monday evening. The president for the year, Mr. Geo. Herbert Strutt, ex-Light Sheriff of Derbyshire, delivered a brief inaugural address at the opening conversation given by the Mayor, councillor Cornelius Boam, in the Albert Hall of the Mechanics' Institute. The exhibition of photographic apparatus, pictures, etc., to say nothing of the musical romenade, light refreshments, etc., were greatly enjoyed by the large number of ladies and gentlemen present. The exhibits include contributions by Kodak, Limited, and the Platinotype Co., and a series of unframed prints, the work of members of the Convention. The exhibition of professional work by members of the Professional Photographers' Association, on view at the Corporation Art Gallery, is also attracting much attention. A review of this collection will be given in our next issue. The week's programme of excursions to the beauty spots of Derbyshire is being favoured with delightful weather, and we doubt not will result in a good "bag" of pictures. At the meeting on Wednesday Professor Joly was elected president for the ensuing year, and Dublin was decided on as the venue for the next convention, in July, 1905. Those who visited Dublin on the occasion of the 1894 convention will retain very pleasant memories of Ireland's capital.

New Lens. The paper recently read before the Royal Photographic Society by Mr. Conrad Beck, on Dr. Rudolph Steinheil's new principle of lens construction, must again impress on us all the pre-eminence of the German in matters connected with the advancement and application of optical science. The photographic objective, the microscope, and the telescope all owe much to our Teutonic brethren, whose peculiar adaptability

for steady research in any particular direction forms a not inconsiderable phase of the national characteristic. We reproduce Mr. Beck's paper on another page, and the lens he describes at length will be found to embody some novel optical properties, not the least of which is its simplicity of construction coupled with the skill with which certain conditions necessary to the construction of the modern anastigmat have been complied with.

* * *

Espionage in Germany. We have two or three times lately called attention to the "spy scare" in France, and cautioned tourists with their cameras to be careful as to how they use them. This caution also, it seems, is equally applicable to Germany, at least, on the French frontiers, for here the authorities are equally on the alert. The Berlin correspondent of the "Standard," telegraphing one day last week says that the trial of a man at Leipzig had been commenced on a charge of espionage. It is alleged that he had obtained employment at Metz in order to obtain access to the forts at Distenhofen, of which he took several photographs. Three high police officials, it is stated, said that they could only give evidence if the trial was conducted in camera. The accused asserts his innocence. We refer to this matter simply to point out that the German authorities are equally as suspicious of suspected spies as are their French neighbours on the frontier.

* * *

Duelling and Photography in France. Duelling in France often brings a smile in England, where we have quite a different and more impromptu method of settling temporary quarrels—namely, with Nature's weapons. A little while ago we read in one of the daily papers, sarcastically inclined, that the French Government should take steps to stop this silly practice or some day, perhaps, an accident would happen, and someone might be hurt. In the daily Press, one day last week, we read that a duel was fought in Paris at the great wheel close to the Champs de Mars, and that it was witnessed by a large number of people, including several photographers, who took cinematographs of the encounter. One of the combatants is said to have been injured. Reading this, and knowing, as we do here, how some cinematograph pictures are produced, many may, taking the circumstances into consideration, fairly surmise that this was a "bogus" affair, got up for the purposes of obtaining a sensational cinematograph picture for a music-hall. But, after all, it may have been a "real genuine French duel," and "honour was satisfied."

* * *

Photographs by Wire. It has long been the dream of electricians to transmit pictures by wire, and several good attempts have been made to realise it. The

latest is by a German physicist, named Korn. His system, which is briefly described in the "Electrician," like most of those that have preceded it, depends on the remarkable property of selenium of permitting or resisting the passage of an electric current, according to the amount of light falling upon it. At one end of the wire a negative photographic film of the design to be forwarded is mounted on a glass cylinder. As this cylinder revolves a spot of light travels over the surface of the film and illuminates a selenium cell behind it. When the beam strikes a transparent part of the negative, the selenium, being strongly lighted, sends a strong electric current, and on the contrary the current is weakened when the light falls on a darker part of the film. At the receiving station, by a reverse arrangement, the sensitive paper on a corresponding rotating glass cylinder is traversed by a fluctuating beam of light, which thus produces a photographic record resembling in light and shade the original design. The apparatus can, it is claimed, be employed to transmit photographs and drawings.

* * *

The Free Portrait Swindle.

From an account in the "Photographische Correspondenz" we are glad to see that one of those people who trade upon the credulity of the public, and do harm to photography, has received his appropriate reward. A dealer of Polish extraction, 35 years old, named Löbmann, but now a naturalised French subject, was charged at Berne with fraud and attempted fraud. His practice was the solicitation of orders for enlargements, which would be made free of cost provided the persons paid for the frames, half the amount on giving the order and the other half on delivery of the framed picture. About twenty tradesmen gave him orders. The frames were of common quality and the pictures not retouched. Löbmann was evidently making a good profit on his venture, for it was proved that he had bought fifty rejected frames from a man in Berne, to whom he gave instructions to pack them and send them to various people, who were informed that the photographs would be sent from another town. The Court found that Löbmann's business was carried on merely as a means of deceiving the public, and as he had already been kept under detention for a month, sentenced him to thirty days' solitary imprisonment.

* * *

Kew and Brentford as Photographic Resorts.

Last week we made reference to the proposed disfigurement of one of the pretty little islands in the Thames, facing Kew Gardens, by converting it into a place for repairing and building barges. A very large number of photographers who dwell in our Metropolis seem to be quite unaware of the pictures they may obtain in the district of Kew and Brentford. Indeed, it would be difficult to find anywhere within four or five miles from the Marble Arch so much food for the camera as here. For example, there is Strand-on-the-Green, commencing from Kew Bridge, where, within two or three hundred yards, a good day's work may be found. The old and varied cottages on the river-side, some quite Dutch in their character, make excellent pictures. In fact, Strand-on-the-Green, with its old barges, is quite characteristic of a Dutch quay. It is the happy hunting-ground of painters, and we have on a fine day seen nearly a dozen at work at one time, but not a single photographer. This picturesque spot affords pictures both morning and afternoon. How long Strand-on-the-Green will retain its present character it is difficult to conjecture, seeing that a year or two ago some of the old cottages were pronounced by the local sanitary authorities to be in an unsanitary state. Then there is the old town

of Brentford adjoining, that with its old date character little cottages and courts, old-fashioned public-houses, of which there is a plethora—together with the barges the river-side on to Isleworth, where several days' work may be profitably expended with the camera. On more than one occasion we met the late Mr. Norman Macdonald the painter, on his way to the salubrious (?) town of Brentford, with his camera, as he told us, to secure "bits" from the old cottages, courts, and squalid children of the "barges" for his pictures. Although Brentford, according to the books, the county town of Middlesex, cannot be said that in its present state it is any great credit to it. But that is of no moment to the camera worker, so long as he can get picturesque pictures there and he can; and, what is more, with a pleasant bus or tram run within half-a-dozen miles of the Marble Arch.

* * *

Coloured Photo-Miniatures.

Photography practically killed miniature painting of the old style on ivory some fifty or sixty years ago, and those who followed it as a livelihood had, perforce, to take to colouring photographs. In the fifties and sixties there was considerable run on tinted and coloured photographs; the work being executed by the old miniature painters who, for the most part, exceedingly well done, and good, many cases high, prices were paid for them. When the carte-de-visite became the rage, the colouring of photographs became neglected, and furthermore the fashion in portraits in brooches, lockets, and the like died out. Hence coloured miniatures became a thing of the past. A few years ago an attempt was made to revive miniature-painting, and a Society of Miniature Painters was formed, which held one or two exhibitions, which were very successful. The King has always shown great interest in the art of miniature-painting, and has now conferred upon the Society of Miniature Painters (at the Modern Gallery in Bond Street) the title of "Royal." This honour should add further stimulus to miniature-painting. At the present time many of our leading portraitists are making a feature of coloured miniatures on a photographic base, and exceedingly well executed many of them are. In the old days the colouring had to be done on silver prints, and not a few, for which high prices had been paid, rapidly faded and that brought discredit to the art. Now, however, we have permanent processes—platinum and carbon—to work upon; hence there need be no fear of the pictures fading. Unfortunately, there is no method of producing a photograph direct upon ivory, the material that the artist most delights to work upon. Carbon prints can be transferred to ivory, but then it is necessary to have a substratum of insoluble gelatine. Hence the artist has not the bare surface of the ivory to deal with, but one of gelatine, which, for his (or her) work is quite a different thing. It remains to be seen if three-colour work, for portraiture, will be brought to such a state of perfection as to supersede hand colouring. So far as we have been able to ascertain, professional portraitists are taking no interest in this subject, though it might well be worth their while to do so. There is little question that if good three-colour portraits were produced, a certain portion of the public would, even for the novelty of the thing, prefer a "natural colour" photograph to a hand-painted one. Up to the present, however, we have seen nothing in this direction that would compare with a well-executed hand-coloured photograph.

* * *

The Heat Wave.

The year of grace 1904 will acquire fame in history for the resurrection of summer—a season loved long since and lost awhile to the energetic

photographer. A glance at the weather reports all quarters during the past fortnight, as published in daily papers, reveal an almost unparalleled series of unbroken sunshine. That this portends much future of plates goes without saying, and incidentally the owner of the small hand camera, fitted with cheap and small stop, his opportunity. He can even aspire to successful street photography, that is, so far as the exposure of the plate goes, under the conditions that prevailed of late. At midday on Monday last we had a fully-exposed negative in the midst of the traffic with a camera having a lens working at F.11 shutter at 1-100 sec. The vast amount of brilliant light at present gives an opportunity for effective street photography that has seldom occurred for many years, not only from the photographic point of view, but also from the social standpoint. The streets have become a study for. Symphonies in white and the palest of pinks and yellows and a dozen other tints adorn the side walks and bus tops. Panamas and flannels and muslins have come up in the streets with the speed of mushrooms. Parks and open spaces are thronged with ladies and men dressed in charming summer costumes; while the lower class, has subsided mostly into grey as light as air. The Water Carnival at Henley, too—that of the snapshotter—reached its zenith in the most beautiful weather. The festive array of house-boats and barges on the course, the panorama of ever-shifting small boats and one types of faces, the whole of the scene, with its charming natural setting made it a year a picture hard to beat. The Meteorological Office wisely will not pledge its word for more than four hours, but we understand that at the Victoria Establishment there was a unanimous feeling at the end of the week that the weather was at last going to credit. It has had so many disappointments during the few years, that a spell of orthodox summer weather is gratefully and comforting to a deserving body of servants, whose efforts are sometimes derided. And the really keen user of the camera, who rides his bicycle under all conditions, will conclude that cooler days and their compensation when the time comes to retire to the stuffy recesses of the dark-room, with the temperate something—a state of things calling for the application of ice, alum, formalin, and much good. Whether all these are possessed by every enthusiastic amateur photographer and the professional with a desire to fill to time is a question we prefer to leave individual.

* * *

Sir William Crookes has been making a series of interesting experiments on the behaviour of diamonds when subjected to the action of radium. More than twenty-five years ago it was found that these gems, when exposed to the impact of matter in a high vacuum, exhibited phosphorescent of different hues, and eventually were, under bombardment, blackened on the surface. This was quite superficial, and was presumably due to the formation of graphite. It could be removed by the action of diamond dust, as in the operation of polishing, or would disappear if the stone were immersed in a mixture of potassic chlorate in strong nitric acid, as the β rays of radium have the same power as the cathode stream in a radiant-matter tube, Sir William thought that it would be interesting to ascertain whether they would bring about a similar change in the diamond. So he selected two small stones for experiment, one of a yellow tinge, or, as a jeweller would say, "a fair." One of these, which we will call A, was

studiously kept out of reach of radium, but the other one, B, was submitted to its influence for seventy-eight days. At the end of this time it was found that B was not only darkened in tint, but that it had changed its colour from yellow to blue. It was now treated for ten days with the acid mixture already described, when its dull surface colour given by the radium disappeared, and it was once more bright and transparent. But it had completely lost its yellow tinge, and was now of a pale blue-green. "This alteration of colour," writes Sir William Crookes, "may be of commercial importance. If 'off-colour' stones can be lightened their value will increase, while if the prolonged action of the radium is to communicate to them a decided colour, they would be worth much more as 'fancy' stones." This discovery by one of our leading scientists will be of service in answering the oft-repeated question of the utilitarian mind with regard to radium, "Of what good is it?" And it will most surely arouse the interest both of those who own diamonds and those who deal in them. We remember once being shown two very fine gems, one being perfectly white, "of the purest water," as our grandfathers used to express it, while the other was a pale straw colour. But this slight colouration made all the difference in the value of the two stones, the white one being worth fourteen times as much as the yellow one. There must be many thousands of these off-colour diamonds scattered about among different owners, and if they can be made white by a few weeks' association with a tube of radium bromide, and an acid bath to clear them, there will be rejoicing in Hatton Garden and elsewhere. Then there is that other question of "fancy stones." It is not, perhaps, generally known that diamonds have been found of all sorts of vivid colours, bright blue, green, and red being among the number. It seems quite possible that by a more extended exposure to radium some of those colours might appear. Such coloured diamonds are not only very beautiful, but they are so rare that they fetch an enormous price. Radium is not likely to get cheaper under the stimulus of this new demand for its kind offices.

* * *

War Pictures.

Although newspaper correspondents and artists are excluded from the zone of fire which is encircling the fortress of Port Arthur, we may reasonably assume that photographs illustrative of the great drama now being enacted in the Far East will be at some time available to the historian. The Japanese, who have shown such marvellous sagacity in adopting all kinds of scientific aids to the needs of war, not even excluding wireless telegraphy, which is hardly yet out of its swaddling clothes, are not likely to miss any opportunity of employing the camera where photographic records may be desirable. Such pictures would be of intense interest to the whole world, for they would illustrate events which are making history and altering the map of Asia. At present we have to depend upon word-paintings for our notions of what is going on, and the canvasses are necessarily small to be written within the compass of a rigidly censored telegraphic despatch. There are the illustrated newspapers, certainly, but even they have to content themselves with the portrayal of minor incidents which occur on the fringe of the battle area, or give confessedly imaginary pictures of the heat of the conflict. What we all want to see are pictures of the fortifications round about Port Arthur with the siege-guns in position ready at the supreme moment to launch their monster projectiles upon the devoted fortress, and upon the harbour which contains nearly all that remains of the Russian Navy. A comprehensive photograph of the area involved would manifestly be impossible unless the operator were up in a balloon, and even a photograph so taken

would only be a patchwork map with detached puffs of smoke of tiny dimensions for each big explosion. We are all apt to take our ideas of a siege from what our imaginations have gathered from the ruined feudal castle or the mediæval romance. But a modern attack on such a place as Port Arthur is a very different operation, for it covers many square miles of country. Do we realise this when we read that the Japanese have secured heights from which their siege guns will be able to dominate the harbour? These heights are in reality five miles away, and it is impossible for those not trained in the arts of modern warfare to realise that from such a distance a deadly fire can be concentrated on the ships in Port Arthur harbour. The Japs have among them expert photographers, as they have experts in every other branch of science and art, and we may be quite sure that all that is possible to the camera will form the subject of photography. The crude prints in colour which found their way over here from Japan during the war with China will not satisfy the needs of such a rapidly advancing country as that of the Mikado, and we may expect photography, with all its limitations, to take a forward place in illustrating events connected with the present struggle.

Black and White.

* * *

"Can the Ethiopian change his skin?" is a question which was asked many centuries ago, doubtless with an inflection of the voice which compelled an answer in the negative. But this old question seems to crop up regularly in America, where people seem to have a kind of idea that it should be answered affirmatively. Not many months ago we alluded to certain experiments which were to be tried with a view to demonstrate that a nigger child, which is white at birth, could be made to remain white if for some weeks it were kept under the influence of non-actinic light. The result of that experiment does not seem to have been published, so that we may presume that it failed, otherwise by this time we should have had that baby appearing at all the music-halls. Another sensation of a somewhat similar kind was alluded to by the New York correspondent of the *Daily Telegraph* a few days back. Silas Ward, who is a negro, is, we are told, gradually losing his dusky colour, and is becoming white. It is believed that fright has produced the transformation which, if it continues, will cause him to become completely blanched. The cause of his fright is not quite apparent. He has been arrested for stealing chickens, and was imprisoned at Long Island; but whether the chickens frightened him, or he became chicken-hearted when pursued by the myrmidons of the law, does not transpire. Whatever may be the cause, this particular Ethiopian is changing his skin as easily as the common Ethiopian serenader of the Christy Minstrel type was able to wash off his burnt cork, and it would be extremely interesting from a photographic point of view to find out the reason for the change. Fright, and excessive grief, have been known again and again to discharge the pigment from the hair, and it seems to be only a short step further to bring about a similar change with the skin. Hydrogen peroxide acts upon the hair in the same way, only it leaves the head golden instead of white. Ladies with dark complexions who have dallied with peroxide do not realise until too late how ill a dark skin looks with yellow hair. To such misguided ones the story of the New York negro will be of especial interest, for it will raise hopes in their minds that skin can be made colourless as well as hair. If any body of men are qualified to deal with a black and white problem such as this, photographers are they, and it would be to their interest to devote some of their leisure time to its study. They already know so much about carbon and other pigments, and are so familiar with various methods

of reduction and intensification, that it should not be difficult to apply to the human epidermis remedies which have been found so effectual in dealing with animal gelatin. If visitors to a studio can have their faces retouched, improved, as well as the presentment of those faces on negative film, photographers will no longer complain of lack of custom. If it be possible to turn a nigger white it should be an extremely easy matter to make a dark complexion a few shades lighter.

THE PHOTOGRAPHER AND HIS EYES.

ALMOST every trade or profession has some special disease peculiar to its votaries—the clerk has his writer's cramp, the lead manufacturer and the potter their lead-poison, the match-maker his necrosis of the jaw, the submachine-gun excavator his "caisson disease," and "dentist's palsy," "miller's itch," the "cyclist's stare," the "athlete's hump" are self-explanatory familiar terms all expressing the same idea, and, while already in photography we often hear of bichromate and metal poisoning, there seems danger of another morbid condition being associated with photographic operating—the retoucher's eye or photographer's retinitis or conjunctivitis. As bearing upon this probability we would draw attention to a note warning struck by Mr. William Sugg at the concluding meeting of the Institution of Gas Engineers recently held. Mr. Sugg spoke of the danger that threatened the sight of the modern worker by artificial light, owing to the increased power of gas-light now so common through the introduction of the incandescent burner without stop being taken to guard the eyes from the effects of the rays known to be deleterious in their action. What he wanted, he said, was that the rays from these burners should be the colour of sunlight, and not that of mercury light. Shades of rose colour or green should be employed where intense light was used. The whole matter needs careful study, was his opinion. It is scarcely necessary to state that the warning is equally applicable, indeed, more so in the case of electric lighting. The views we are expressing cannot be looked upon as alarm, will be obvious to all readers of our Correspondence Column, files of which will show by no means infrequent reference to the existence of eye troubles, and any one who observes the retouchers at work with the consoling glare of a bright light—frequently the actual incandescent light referred to in Mr. Sugg's warning—must be struck by the very present danger to the ultra-sensitive organ, sight that such exposure must bring about. Dr. Sverdrup Wells, long known as a leading ophthalmologist, in his work a "Treatise on Diseases of the Eye," states that "Retinitis is but rarely met with as an idiopathic affection, but . . . it is probable that it may be produced by prolonged exposure to extremely bright light . . . or by excessive use of the eyes, especially by strong artificial light. At first, only a hyperæmic condition of the optic nerve and retina is noticed, and then, if the employment is persisted in, retinitis may ensue." There can be little or no doubt that it is at this stage of hyperæmia of the retina that the retouchers who have written to us have experienced the first feelings of alarm, and it is at these instant steps should be taken to avoid subjecting the eye to further grave risks, until medical advice has been sought. Simple conjunctivitis, or, as Dr. Wells prefers to call it, catarrhal ophthalmia, is also liable to be produced by the same cause, as he states in another portion of his "Treatise," again using almost the identical words we have quoted above as to its causation. We earnestly desire to call our readers' attention to another source of possible danger to eyesight, one v

to be overlooked—the continual glare upon the eyes of red light of the dark-room lamp during development, it is unsuitably situated, or from which the eyes are protected. It might be thought that the light would be screened, if merely because of the fact that a perception of the finer qualities of the image is not possible if the eyes are exposed to a strong light, especially if the light is of a red colour; but we must say that of the many dark-rooms we have entered such screening is a very rare exception. We commend to our readers the method adopted by Mr. Ives in the dark-room he occupied when stationed in London some years ago. That photographer, most fertile in practical expedients of almost any kind, we have met, had a strong red light placed immediately in front of him, but he was wise enough to prevent its direct rays entering his eyes, and this he effected in a way as simple as it was efficient. He will, we are sure, forgive us for betraying the secrets of his dark-room. Between the eyes and the light he had a slight screen fixed by hinges to the wall, and capable of being lowered, or raised, almost to a perpendicular position if required, so as to enable him to uncover the light when it was desired to look through his negative by its direct aid, and to hide it again when not directly needed. We may add further detail—though unconnected with the subject we are dealing with—the under side of this screen was painted of a bright colour, so as to throw down upon the plate in its developer a soft and even illumination. Prevention is better than cure, we are apophthegmatically told. This is prevention in one direction; in the other, retouching is a plan adopted by one of the very earliest retouchers who was at work over a quarter of a century ago contains some of the most desirable precautions. He used a lamp as his source of illumination, and concentrated the rays by passing them through a globular water-bottle, in which, and here lies the point, was faintly dissolved water by washing out into it a sable pencil that had been used across the cake of indigo in his colour-box. With the facilities which modern photography offers a less cumbersome substitute would be found by dyeing a waste dry-plate (from which the image had been removed) to any tint that was suitable, and this we are inclined to think might have been chosen green, rather than blue. A penny tin of Judson's dye of the desired tint could be had at any druggist's or chemist's shop.

To cure, our advice to anyone intending to "doctor" himself is that of Punch's—"Don't!" Above all things, eyes should not be tampered with when they give warning of trouble; a medical man should be seen. When, however, nothing more is experienced than a temporary inconvenience, an innocent collyrium may be made by dissolving boric acid in water in the proportion of about four grains to the ounce, and applying it with a soft rag or sponge, or, what is far better, an eye-cup. Our own method is to make it double this strength and dilute with hot water just before use, to make it quite over "milk-warm." It is then most pleasant in application.

THE tribute to literature and its power of "taking you out of yourself"—where we all want to be—is paid by a "Librarian" in the "Book Monthly." He writes: "Every sort of article is found turned circulating library books—photographs, hairpins, powder, love letters, bills, bits of lace; in fact, anything that will serve as a book-marker, from a slice of bread and jam to a five-pound note." It would like to know the name of the novel that so fascinated a reader that it was worth a fiver not to miss a word.

A NEW PRINCIPLE OF PHOTOGRAPHIC LENS CONSTRUCTION.

[A paper read before the Royal Photographic Society.]

IN bringing before your notice the new invention by Dr. Steinheil of Munich in photographic lens construction I do not propose to-night to describe the qualities of the new unifocal lens which may be more suitably studied in our commercial publications, but I shall endeavour to set forth what appears to be one of the most original steps in lens construction that has been seen for many years.

Fig. 1.

To begin at the end, as it were, I will mention that this new lens consists of two convex positive and two concave negative lenses which are all four of the same focal length and which are all four made of glass with the same mean refractive index. It is, in fact, this feature which suggested the name Unifocal for the lens. Such a combination does not look at first sight very hopeful, and would appear to give but slender chances of producing a corrected lens at all. The two convex might be expected to neutralise the two concave lenses of equal power and the correction of spherical aberration with glass of the same mean refractive index would appear to be impossible. But, leaving this problem, let us first examine the means by which the colour correction of a lens of the usual type is accomplished, and, in order to somewhat simplify the problem, let us consider the case of a telescope object glass. With this form of lens, which consists usually of a convex positive lens in contact with a concave negative lens, the colour correction, or, more technically, the correction for chromatic aberration, determines the focal lengths that the two component lenses must have. That is to say, the positive and negative lenses must be in a definite ratio according to the dispersion of the glasses employed.

Fig. 2.

To illustrate this point the first lantern slide shows a plain convex positive lens marked I. with a ray of parallel white light entering from the left. The lens bends this ray of light upon emergence, but, owing to the well-known property of glass which is called dispersion, it acts differently upon the different-coloured portions of light which, when combined, go to form a ray of white light. A lens or prism of glass will bend blue light more than green, green more than orange, orange more than yellow, and yellow more than red. For sim-

plicity the lantern slide shows only the red and blue light, but it will be evident that if the blue light is bent most, it will come to a focus on the axis at a point nearer to the lens than the red. The diagram therefore illustrates these two positions, and if a bundle of parallel light entered an uncorrected lens, it will not for this reason form a sharp focus on the axis at any one point.

On the same lantern slide is a figure of a concave lens marked No. 2 of the same power and made of the same glass, and in this a small bundle of white parallel light is supposed to be entering from the right; this lens splits it again up into its component colours, the blue being again more bent than the red and emerging from a virtual focus nearer to the lens than that of the red. Indeed, the positions of these foci are exactly the same as those of the convex lens, because we have assumed that the lens is of the same power and the same glass.

If now we close these lenses up together it will be noticed that the negative lens exactly neutralises the colour errors of the convex lens, and the light emerges as white light. The blue light emitted by the convex lens proceeds along the exact course that is necessary in order that it should emerge from the negative lens in a parallel direction, and the red light does the same. But the colour error being thus neutralised is accomplished at the expense of the whole lens being neutralised, and the combination is useless, the light passing through it without being bent or focussed. If we use a negative lens marked No. 3 that is not as powerful as the positive we shall then find that the convex lens is only partially neutralised, and we still have the light refracted. But we shall also find that the chromatic aberration is only partially neutralised, and in fact such a combination is no better than if we had taken a less powerful uncorrected convex lens.

If, however, we use a glass for our negative lens marked No. 4, which has a greater dispersion, that is to say, that has a greater power of separating the colours, we can neutralise the error of the convex lens without entirely neutralising its refractive or bending power. Let us suppose that a negative lens is made of such a glass and of such a power that it bends the red light to the same extent as before, but bends the blue light more. With a suitable selection we could arrange that it bent it to such an extent that, although it is not so powerful a lens as the convex, it exactly neutralises the colour error. If the glass of which the negative concave lens is made displaces the colours twice as much as that of the convex positive lens, or indeed has double its dispersion, then it need only be half as powerful a lens to correct the chromatic aberration, and the result of such a combined pair of lenses is to produce an achromatic lens half as powerful as the original uncorrected lens. This is the principle upon which the telescope object glass and most forms of photographic lenses are made. The individual lenses are in the ratio of the relative dispersions of the glasses employed. Now as there are many kinds of glass available, and therefore many different dispersions, it might be supposed that there is a considerable choice of focal lengths for the individual convex and concave lenses in order to produce the particular complete lens required. To take a simple case, suppose we require to produce a 10 in. achromatic lens, by means of a positive and a negative lens cemented together, it can be made with a plus 1 in. and a minus 1.9 in. lens cemented together, provided the two glasses save the difference in dispersion of 1 to 1.9, or it can be made with a combination of a plus $4\frac{1}{2}$ in. lens, with a minus 7 in. lens, another pair of glasses being selected which possess this greater difference in dispersion. So that one might take a pair of extremely powerful lenses or a pair of comparatively weak ones, and yet obtain the required 10 in. achromatic lens. If this be so, it will be readily seen that the less powerful lenses are the better, because the curves are less deep. Spherical aberration and many of the other

errors of a photographic lens increase very rapidly as the curve become deeper, and, although such errors can be corrected, is with difficulty, and prevention is better than cure. Absence of body is always better in a railway accident than presence of mind, so it is better to use the lower power components, make the achromatic 10 in. lens, rather than the powerful ones, and in a telescope objective this is generally done.

But, unfortunately, in photographic lens construction another factor comes into play, although the component lenses require to be of certain special focal lengths to produce achromatism, they require also to be of certain focal lengths to give a flat field free from astigmatism, so that there are two considerations that bear upon the focal power of the lens employed. They have also to fulfil a formula which is called the Petzval condition which says that—

$$\sum \frac{1}{\mu F} = 0$$

or expressed for two lenses $\frac{1}{\mu_1 F_1} + \frac{1}{\mu_2 F_2} = 0$

or written differently

$$\frac{F_1}{F_2} = -\frac{\mu_1}{\mu_2}$$

This means that the component positive lenses of a photographic lens must have a focal length that is in a ratio to that of the component negative lenses equal to the refractive indices of the glasses used. That is to say, in the 10 in. lens previously mentioned, not only must the focal lengths be in the proportion of the dispersion, but also in that of the refractive indices of the glasses employed. Now, although there exists great difference of dispersions in glass, there is not much variation in refraction, and the greatest difference in this respect in glass that is otherwise suitable is between about 30 and 33. Therefore the focal lengths of the positive and negative lenses must be in about the ratio of 30 to 33. If this is worked out by the ordinary formula for obtaining the resultant focal length of a number of lenses close together, it will be found that to produce a lens of 10 in. focus, the positive lenses must have a focal length of only three-quarters of an inch, and the negative lenses only slightly more.

Fig. 3.

To render this point more clear, I have prepared a mechanical slide. The formula which tells us what are the focal lengths of two lenses in contact which will give us a particular focus resultant lens is $\frac{1}{F} = \frac{1}{F_1} + \frac{1}{F_2}$, and the answer to this equation can be obtained by a diagram.

If we divide off a vertical line in inches and a horizontal line in inches, and swing across these divisions a line which revolves on a centre which has been correctly placed, the position where this line cuts the vertical divisions gives the focal lengths of the positive lens, and where it cuts the horizontal divisions gives the focal length of the negative lens.

The lantern slide is designed for producing a complete lens of 10 in. focus, and it will be seen that it can be constructed out of a positive of 7 in. focus and a negative of $22\frac{1}{2}$ in. focus, or out of many other combinations. But suppose that the positive and negative lenses have to be in a particular ratio, say, one must be twice the other, then the focus that the two component lenses must be is at once fixed. There is only one position of the swing line where this exact ratio is found, and

are the foci of the lenses and no other. You will also see if the difference between the foci of the positive and negative lenses is great, the focal lengths are comparatively long. The ratio is 2 to 1, the positive lens used for making a camera lens 10 in. lens can be as much as 5 in., but on the other hand, if the two lenses have to be more nearly similar, if the positive and negative focal lengths must be very similar they must both be enormously powerful short focus lenses.

You have just seen then that for the satisfying of the Petzval condition which is necessary to produce an Anastigmat lens of positive and negative component elements must be very nearly the same in power, a variation of about 30 to 33 being required to satisfy the Petzval condition, and this can only be done by having both the lenses very powerful. It will be seen at once how greatly this complicates the problem of making the corrections. The modern Anastigmat has been constructed in most cases by the combination of a series of extremely high power positive and negative lenses, each individual lens having large errors of a positive and negative nature. This has involved deep curves and a large number of elements to obtain the required perfection.

There are six chief errors to be corrected in a photographic lens: (1) chromatic aberration, (2) spherical (central) aberration, (3) astigmatism, (4) curvature of field, (5) coma, (6) distortion, to combine all these corrections simultaneously in one lens is unusually difficult. The usual methods of effecting corrections have been No. 1, chromatic aberration, by the choice of lengths of the component lenses according to the dispersion of the glass, Nos. 3 and 4 by the focal lengths of the component lenses according to the refractive index of the glass. Nos. 3 and 4, however, are also dependent on the actual shapes of the lenses. Nos. 2 and 5, spherical aberration and coma, must be made by altering the shapes of the lenses without altering their focal lengths, and combinations that can be devised to simultaneously make the whole corrections are consequently difficult to obtain. These remarks are necessary to point out the astonishing advance which has been achieved by Dr. Steinheil, who, by one stroke, has swept away from the problem the Petzval condition. He has invented a method of making all the foci of the component lenses the same and mean refractive index of the glasses of which the component lenses are made, also same. So that, whatever the foci of the component lenses whatever the refractive index used, the Petzval condition

$$\sum \frac{1}{\mu F} = 0$$

is satisfied.

As soon as this exasperating restriction has been withdrawn, anastigmats have to be made of unusually high power lenses, the positive being balanced against the negative, the refractive index to be used is extended. It is no longer necessary to introduce large spherical aberration and errors which must be corrected; they can all be reduced to a much lower grade before the correction is attempted. It is, however, objected that to compound a lens of a positive and a negative of the same power may remove the Petzval condition of astigmatism, but it will also remove all refracting power, and render the combination useless as a lens.

You have just stated that such would be the case, and to avoid complication I have not mentioned that if we take a positive lens of 1 in. focus and a negative (minus) lens of 1 in. focus, they only neutralise each other if placed close together. I have prepared a lantern slide which shows a negative lens and a ray of light entering from the left in a direction towards the virtual focus of the lens, and in consequence the light, when it has passed through, emerges in a direction parallel to the axis, but the slide is so constructed that if the direction of the entering ray of light is altered, the direction of the

emerged ray will be altered also in the same way as it actually happens in optics. Thus, this lantern slide shows the positions of any pair of conjugate foci of a negative lens mechanically, and forms rather a simple means of showing what happens in actual practice. As one focus gradually approaches the lens, the other follows it, but at a very different speed.

Fig. 4.

I will now introduce a convex lens of the same focus as the concave, showing a parallel ray of light being brought to a focus on the axis. If the convex lens be placed in contact with the negative, the exact neutralisation of the pair is shown, the light that leaves the convex lens being sent out parallel again by the concave, but suppose I separate the two lenses a little I can ascertain by the mechanical contrivance of the slide where the ray being emitted by the convex lens will be focussed to, and we find that the neutralisation no longer takes place. The combined lens is now a fairly powerful lens, focussing parallel light down to a point on the axis not far from the lens. Thus, if the negative lens be gradually moved away from the positive, it has less power as a lens and will act as if it were no longer focus, so that by making the separation between the component positive and negative lenses to the required amount, the chromatic aberration can be corrected exactly as if the negative lens had the required difference in focal length. The complete combination, instead of being a neutral non-magnifying lens, as would be the case if the component lenses were close together, has a positive focus. The rest of the corrections are made by the shapes and focal lengths of the individual lenses, without, however, being hampered by the restriction imposed by the necessity of carrying out the Petzval condition in the ordinary manner. The lenses are made very thin with very flat curves, and consequently do not give rise to the reflexions which produce flare and reduce so largely the quantity of light that enters the lens. With a Unofocal lens having an aperture of F.4.5 most perfect photographs can be taken with small stops, and, astonishing as it may appear, the F.4.5 Unofocal lens may be used stopped down as a perfect wide-angle lens.

The exasperating restriction that the Petzval condition introduces in the manufacture of anastigmat lenses has hitherto required that some compromises must be made. All the defects cannot be corrected with the same amount of perfection, but, this restriction being removed, it has been possible to produce a lens of F.4.5 with telescopic central definition, perfect freedom from distortion and flare and a 60 degree flat field, of which this lantern slide shows the astigmatism. The chart is measured from an actual lens.

Astigmatism Charts.

Fig. 5.

A somewhat curious but very useful advantage that is gained by the use of a lens of this Unofocal type is the greater equality of illumination over the whole plate which it possesses. The diagram shows two lenses, in the upper one of which the two

concave lenses are cemented to the convex, and in the lower one they are placed at some distance from them. It will be noticed that, owing to the coming down of the light in the lower diagram by the convex lens, before it reaches the concave, a much larger proportion of an oblique pencil of light gets through. The diagram is somewhat exaggerated, but not so much as might be generally supposed. The methods by which all the other various corrections of the Unofocal lens are accomplished are worked out by calculation and could not

Fig. 6.

well form the subject of a paper, but the principle of removing the Petzval condition from the calculations in this ingenious manner has appeared to me of sufficient interest even to those who are not frequently calculating lenses to warrant my bringing the matter before your notice. The use of separated lenses is of course not new, but the same trouble of complying with the Petzval condition occurs, and it is only Dr. Steinheil's invention of using equal foci and equal refraction index glass that has solved this problem.

CONRAD BECK.

SAFEGUARDING THE LENS.

By the AMATEUR OPTICIAN.

THE extent to which a photographic lens may deteriorate by the action of light has been a matter of conjecture and experiment, rather in years gone by than recently. It seems to be a fact that lenses—photographic combinations—say of the rapid series, may, it appears, by the discoloration of the glass, become distinctly inferior. The previous generations no doubt felt this matter somewhat acutely at times; the optical portion of the outfit was, on the whole, much more costly than at present, the rapidity of his wet plates depended considerably if not altogether upon the skill and experience of the individual; therefore it is easily understood that when a lens by some cause degenerated in rapidity, to say nothing about any loss in definition which would no doubt be associated with the decrease in speed, the owner thereof would be severely handicapped at the least, and most probably be very much out of pocket.

The late Mr. Traill Taylor may be quoted to the effect that "the great cause of lenses becoming slower is not the balsam used in cementing their elementary parts together, but the discoloration of the glass itself by the action of light." The subject was brought before the British Association (Brighton meeting, 1872) and some samples of fine quality glass shown "which from being quite colourless had assumed a very sensible degree of deterioration on being exposed to strong sunlight under a mask for a brief period. It was felt that this deterioration, although of perhaps primary importance in such a case as the glass roofing of a studio, which was constantly exposed to light, would also effect photographic lenses in which a degree of discoloration far less in amount would produce a greater effect in the prolongation of the exposure." The author continues "To ascertain whether optical glass would follow the role of window and plate glass, we wrapped a piece of tin-foil round a lens in such a manner as to allow one half to be exposed and this we placed

where it could receive the beams of a September sun for a protracted period. Upon being afterwards examined by laying on a sheet of white paper, the exposed half caused the eye to assume a decided hue of a character resembling yellow or a purplish tinge."

We have been induced to remark upon the subject by reason of the regrettable practice adopted by many dealers in photographic apparatus of exposing cameras and lenses in windows, often in a very strong light, with the lenses uncovered. The length of time in strong daylight to which of these optical combinations have been exposed before being put to rest, meeting with a resting place in the pocket of the purchaser, is a matter of pure conjecture; it may be weeks or months. Judging by the condition of a window we pass almost daily, the period of exposure is very considerable. As it is clear that prolonged exposure to light will in some cases lead to the discoloration of the glass objectives, faint it may be, but sufficient to necessitate a longer exposure in the camera, or—for we are better off than formerly—the use of a quicker plate, it is equally clear that the careful treatment of a lens should not begin with the purchaser and operator. We have been taught to treat lenses, some of them costly, and all of value in their respective departments, with care and discretion. A cap for the front sometimes for the back of the lens—which is a good practice—or a neat light-proof case, has been the rule in all well regulated practice, for many years, the precaution being based upon grounds, not only the perfect cleanliness of the instrument, but the protection of the glass against unnecessary strong light. The practice we have referred to is objectionable, unreasonable, is not the design of the makers nor fair to the person who ultimately has to use the apparatus.

PHOTOGRAPHY AS A PROFESSION IN THE UNITED STATES.

THIRD ARTICLE. CERTIFICATES.

These shall consist of employer, all-round workman, operator, retoucher, and printer, each good for one year only from date of issue. There shall be three grades in each—ordinary, honours, and extra honour. The ordinary certificate shall be granted to possession of ordinary technical skill, the honours certificate to knowledge of theoretical principles chiefly.

Those who on December 31, 1904, have been for at least five years engaged in photographic work will be granted ordinary certificates on submitting proof to the board of examiners that they possess fair technical skill in the branch or branches of the art they profess. For further particulars consult special paragraphs.

EMPLOYER CERTIFICATES.

Ordinary certificates.—These will be granted to all photographers in business on December 31, 1904, who can prove to the satisfaction of the examining board that a fair grade of work is being made in their place of business.

Any one starting in business as a photographer after December 31, 1904, will be granted an employer certificate without examination if he already hold an all-round workman certificate, the grade of the new certificate to be the same as he previously held. Should he not hold an all-round workman certificate before he can secure an employer certificate he must qualify by examination in the department or departments in which he is deficient, according to the rules regulating such departments.

Honour and extra certificates.—These will be granted to all photographers in business on January 1, 1905, who qualify by examination in the corresponding grades as operator, retoucher, and printer, and to those who start in business after that date.

no already hold corresponding certificates as all-round workmen, or who afterwards gain it by examination. These certificates may also be granted to holders of the ordinary certificate to gain some very distinctive reputation from a non-professional on account of pictorial excellence.

ALL-ROUND WORKMAN'S CERTIFICATE.

All-round certificates will be granted to those who have qualified in the three departments as operator, retoucher, and printer. Each certificate will state the grade attained in each.

OPERATOR CERTIFICATES.

Ordinary certificate.—This grade of certificate will be granted to anyone who has had at least two years' experience as an employee, on proving to the satisfaction of the examining board that he or she can make the following portraits: Child under seven, full length and bust figures of young man and young woman, family group of not more than five people, mother and child, old man and old woman. The candidate must be able to expose and develop correctly, the negatives to be such as will give good gradation when printed on mat surface paper. He or she must also be able to intensify and reduce negatives.

Honour Certificate.—In addition to the above the candidate must know the chemistry of photography as found in the constitution of a photographic plate, the action of light and developing salts on the same, also the chemistry of the various intensification and reduction processes. Optics.—He or she must be able to draw a figure in line either from life or model, and be familiar with the theory of portrait lighting.

Extra Honour Certificate.—In addition to the above the candidate must possess a good knowledge of the theory of composition and values.

RETOUCHER CERTIFICATES.

Ordinary Certificate.—This grade of certificate will be granted to any one who has had at least two years' experience as an employee, on proving to the satisfaction of the examining board that he or she can retouch equal to the standard required in a good studio.

Honour Certificate.—In addition to the above the candidate must be able to etch on the film, and to make a shaded drawing of a plaster cast of the human head, special attention being given to the principal lines and muscles.

Extra Honour Certificate.—In addition to the above the candidate must be able to name the muscles and bones of the human head, and to make a shaded drawing of the head and bust of a plaster cast, special attention being given to the lines and muscles.

PRINTER CERTIFICATES.

Ordinary Certificate.—This grade of certificate will be granted to any one who has had at least two years' experience as an employee on proving to the satisfaction of the examining board that he or she is able to work both glossy and mat printing-out-papers, glossy and mat printing-in-papers—such as Velox—the brands to be worked being selected by the candidate. He or she must be able to mount prints neatly on any standard mount on the market.

Honour Certificate.—In addition to the above the candidate must be able to make platinum prints—brand to be selected by the candidate; be able to subdue contrasty effects by local printing or otherwise, and to show a knowledge of the chemistry of photography as applicable to silver and platinum printing, and be able to test both silver and platinum prints as to whether they have been sufficiently fixed or washed.

Extra Honour Certificate.—In addition to the above to be able to sensitise carbon tissue, print and develop it, and to be able to explain the chemistry of the process.

APPRENTICES.

Any person entering the profession of photography after December 31, 1904, in order to be eligible for certificates must fulfil the following conditions:—

1. He or she must be sixteen years of age, have attended at

least two years at a high school, and must be able to make direct from the object a satisfactory outline drawing of an ordinary table, chair, or couch.

2. He or she must show a service of at least two whole years—unemployed time shall not be counted—with certificated photographer or photographers. Apprenticeship will be considered as commencing with the date when the preliminary drawing examination was successfully passed and proof of age and school career has been admitted. At the end of the apprenticeship period the various employees' certificates may be attempted at any duly appointed examination and in any order.

Students of any college of photography who have attended a course of at least two years length will be considered as having served the regular apprenticeship, provided they pass the preliminary drawing test not later than the date of attempting their first examination.

METHOD OF GRANTING CERTIFICATES

To those now engaged in photography as a business or occupation.

1. Those owning or renting a studio must send in to the examining board twelve cabinet prints of the following subjects: Two baby pictures, one family group, one group of young people, one bridal couple, one full length and one bust portrait of young woman, one full length and one bust portrait of young lady, one old man, one old woman, and one outdoor group. All labour expended in the production of these prints must be done by the regular studio staff. An examination fee of \$1 must accompany the application. If applicant satisfy the examination board he will be notified to that effect, and certificate will be granted on receipt of the membership fee of \$5. Should the applicant fail to qualify he will be notified of the fact, and suggestions given him as to how he can bring his work up to the standard. He may again make application for a certificate whenever he feels he has attained the necessary skill.

2. Employees must make application to the examining board stating whether it be for an all-round workman, operator, retoucher, or printer certificate, and in their application must give the name and address of their employers for at least two years prior to the date of application. One dollar fee must accompany the application. The examining board will at once communicate with the previous employers to learn the estimation in which the applicant is held as a workman, and from the replies determine whether he is eligible for a certificate or not. In case any applicant who has been refused a certificate feels he has not been fairly treated he may appeal to the board for an examination, and it shall be the duty of the board to arrange reasonable opportunity for the applicant to take such examination within six weeks of the date of his appeal.

When the examining board has decided that the applicant has qualified for the certificate, he or she shall be notified, and the certificate will be granted on payment of \$1.

In case of a certificate being refused, the board may suggest to the candidate such line of study as would help him, and he may apply for future examination as soon as he thinks himself qualified.

PROFESSIONAL Photographers' Association.—A meeting of the Liverpool branch was held on June 24th, with Mr. G. Watmough Webster in the chair. The discussion on the question of photographers' prices was resumed, and it was decided, on the motion of Mr. Mowll, seconded by Mr. Warrington, "That all photographers in Liverpool and district be invited at a later date to attend a meeting, under the auspices of the Liverpool branch of the P.P.A., at the Alexandra Hotel, with a view to ventilating opinion in reference to photographers' prices." It was hoped that local photographers would have the interests of their profession sufficiently at heart to make the meeting a representative one, and one likely to lead to results beneficial to all.

THE INFLUENCE OF THE CHARACTER OF DEVELOPERS ON THE SIZE OF GRAIN OF REDUCED SILVER.

FOLLOWING many works (*) on the subject, it has up to the present been generally admitted that the size of the grain of reduced silver in gelatino-bromide plates is uniform whatever be the developer used.

Abney (†) has, moreover, found that the size of grain of reduced silver in an over-exposed plate is finer than in the case of the same plate normally exposed, and also that additions of alkaline bromide apparently increase the size of the grain.

Having obtained with some less energetic developers very transparent images of a colour differing greatly from the ordinary, we thought that there may be a relation between the size of the grain and the colour of the deposit.

In order to verify this idea we compared for size of grain silver reduced by the principal known developers not only normally composed, but also by experimenting with the same developer in different degrees of dilution, in different duration of action, at different temperatures, and in different degrees of alkalinity. We also investigated the modifications determining variations in exposure as well as the results of decreased or increased development.

A.—INFLUENCE OF THE CHARACTER OF DEVELOPER.

Developing solutions were prepared of normal composition, as usually employed, and with the following developing substances:—Hydroquinone, pyrogalllic acid, dianol, metol-hydroquinone, quinomet, eikonogen, glycin, paranol, ortol, edinol, adurol, hydramine, pyrocatechin.

In addition to the preceding developers, which comprise nearly all the developers ordinarily employed, we have tried others which are seldom used owing to their weak developing power. These latter appeared particularly interesting from the fact that the reduced silver gave them images of special colours.

Examples of these weaker developers are paraphenylenediamine and orthoamidophenol, used with sulphite of soda alone. These developers give by reduction an image of great transparency and of a brownish colour by transmitted light, and grey by reflected light, much akin to that obtained by the development of collodion emulsions. We give the composition of the various developers employed.

With all these solutions we developed lumiere blue lab plates of the same emulsion and consequently all of the same size grain at the start. Exactly identical exposures were made on all, and then followed development in the previously mentioned solutions, all at a temperature of 20 degrees, and in all cases until the developed images had reached a comparable density.

All the plates, after complete washing, were treated on small portion of the surface (that most opaque being chosen), containing the greatest amount of reduced silver) by a little water sufficiently hot to dissolve the gelatine. This gelatin solution, well shaken, and containing the reduced silver, was used for the preparation of material for microscopic examination. The whole of the developed plates were treated in the same manner, and the microscopic images photographed, employing in all cases the same magnification. The prints obtained were compared together, and showed the following results:—

1. The size grain of silver reduced by the different developers in general use appears the same whichever developer be employed.*

2. Developers, as paraphenylenediamine or orthoamidophenol, used with an alkaline sulphite produce reduced silver of an extremely transparent nature and of characteristic colour of which the grain is much finer than that produced by other developers.

B.—INFLUENCE OF THE DEGREE OF DILUTION OF THE DEVELOPER AND LENGTH OF ITS ACTION.

In order to observe the influence of diluted developers we selected normal hydroquinone and carbonate of soda, and also dianol. Each of these was diluted by an equal volume of water in the first test, and by ten times more water in the second. In both cases development was continued sufficiently to produce deposits of the same density.

Plates were also developed in upright baths for about an hour, using quinomet and dianol according to the following formulæ:—

Quinomet.		Dianol.	
Water ...	4 litres.	Water ...	2 litres.
Quinomet ...	5 gr.	Dianol ...	3 gr.
Anhydrous Sulphite ...	50 gr.	Anhydrous Soda Sulphite ...	9 gr.
10 per cent. Pot. Bromide ...	5 c.c.		

The plates were also developed in the same dish with a normal hydroquinone developer containing carbonate of soda, one of which had been taken from the developer and fixed directly to the image was clearly visible, and the other had been sufficiently developed to obtain a dense image. The same trials were made using normal dianol developer.

The negatives so obtained were thoroughly washed, then each treated with hot water as previously mentioned for the purpose of making preparations for microscopic examination. The results of this examination were then photographed as before.

(*) The coating of the plates developed by pyrogalllic acid being insoluble, the gelatine was melted by heat with a solution of caustic alkali, in order to obtain the preparation for the microscope.

The examination of the resulting microphotographs shows that the size of grain is practically the same in all cases, excepting the case of those slowly developed, in which the size of grain is finer than in the others.

INFLUENCE OF THE TEMPERATURE AND ALKALINITY OF THE DEVELOPER.

A series of experiments was made with two developers. Metol and hydroquinone, working with solutions kept at different temperatures—5deg., 15deg., 25deg., 35deg.—and the images produced being developed to approximately the same density.

Observations were also made at the same temperature of the influence of larger or smaller quantities of alkali, by increasing or diminishing the quantity of alkaline carbonate in a series of plates, and by adding to a normal dianol developer increasing quantities of soda bisulphate in order to increase the normal rate of development by rendering the solution more acid.

The negatives obtained in these different experiments were developed so as to obtain microscopic preparations for photographing. In no case was found any appreciable difference in the size of the grain of the reduced silver.

Experiments were also made by adding to a paraphenylene diamine developer (compounded with soda sulphite) increasing quantities of alkaline carbonate. It is noticeable that this action in increasing the speed of development tends to produce a deposit of reduced silver of similar colour to that obtained with other developers. The microscopic examination of images developed shows that the size of grain enlarges according to the increase in the quantity of alkaline carbonate until the normal strength is reached. At the same time the colour of the image becomes more and more black, and finally is comparable in colour with that produced by an ordinary developer.

An experiment was also made by suppressing the alkali in certain developers, such as paranol and hydramine, and by slow development, using only soda sulphite in addition, to ascertain whether by this means results comparable to those obtained with paraphenylene diamine or orthoamidophenol could not be obtained. No more modification, however, is found than when a normal dianol developer is acidified with soda bisulphite. The colour of the reduced silver shows no change.

INFLUENCE OF DURATION OF EXPOSURE AND THE ACTION OF ALKALINE BROMIDES.

A series of plates some under-exposed, some normally exposed, some over-exposed, in different degrees, was developed. The normal developers were employed, viz., hydroquinone with a carbonate and dianol.

The images were developed to a similar density and then developed as in the former cases to obtain microscopic preparation, which were then photographed.

Examination of the microphotographs appears to show, as indicated by Abney, that in cases of over-exposure the grain of reduced silver is slightly smaller than in the case of normal exposure.

Again, plates exposed under the same conditions were developed in two developers very sensitive to the action of alkaline bromides, viz., hydroquinone (with soda carbonate) and quinomet with soda sulphite and acetone. (*) We added to these developers increasing quantities of a 10 per-cent. solution of potassium bromide, varying from 2 to 15 c. c. per cent. of the developer. The images, when developed to similar densities, were treated as before to obtain microscopic preparations. Examination of the microscopic images given by these preparations appeared to show a slight enlargement of the grain of reduced silver when the developer contained considerable additions of alkaline bromide.

Pyrogallol acid developer was not chosen owing to the difficulty of obtaining microscopic preparations from plates so developed, the gelatine of such plates being practically insoluble.

CONCLUSIONS.

We may draw the following conclusions from the preceding experiments:—

1. The size of the grain of reduced silver deposited by normal developers as ordinarily used is practically invariable.

2. No apparent influence is shown on the size of the grain of reduced silver by temperature, concentration, or duration of development.

3. Excesses of alkali or alkaline bromide seem to produce a very slight enlargement of the grain.

4. Over-exposure appears to be a factor towards the reduction of the size of the grain of silver reduced by a developer.

5. Two developers not generally used, viz., paraphenylene diamine and orthoamidophenol, used with soda sulphite, produce a deposit like that obtained when collodion emulsions are used, and of which the grain is much finer than that produced by other developing substances. (*)

6. The colour of the deposit seems to vary in relation to the size of the grain. The finest grain corresponds to a grey violet colour like that shown on the reduced silver of collodion emulsions.

The various developers may be classed according to the increasing size of the particles of silver reduced by them, and show four types of size represented by the accompanying plates. These plates show that the first type presents many important differences to the other three, which differ but little between themselves.

First Type.—Paraphenylene diamine or orthoamidophenol used with soda sulphite only.

Second Type.—Paraphenylene diamine or Orthoamidophenol used with soda sulphite and a small quantity of alkaline carbonate.

Third Type.—Paranol used with soda sulphite only. Quinamet used with soda sulphite only or with the addition of acetone. Paraphenylene diamine used with soda sulphite and a normal quantity of soda carbonate. Normal metol, eikonogen, or other developers (formulae as above).

Fourth Type.—Normal hydroquinone-metol, hydramine, paranol, hydroquinone (formulae 1 and 2), pyrogallol acid, edinol, dianol (or with the addition of soda bisulphite), or quinomet used with caustic lithia (as in formulae above).

A. AND L. LUMIERE AND A. SEYEWETZ.

Photo Jewellery.—Messrs. Dorrett and Martin, of 60, Strand, W.C., and 16, Belle Vue Road, Upper Tooting, London, S.W., have submitted to us specimens and price lists of their productions in photo-jewellery. These little pictures which are produced in great variety of size and style, are placed in metal frames of tasteful design, and make very attractive articles of bijouterie. The needs of the professional photographer are specially catered for by Messrs. Dorrett and Martin, to whom our readers should apply for full particulars of their specialities. In an explanatory leaflet Messrs. Dorrett and Martin observe:—"The photo jewellery line is one that has assumed vast proportions in America and the Continent, and is now making gigantic progress in the Colonies; therefore it is only reasonable to suppose the same will take place in this country. The reason of this success is not far to seek, for what could be nicer, as a present or ornament, than a suitable piece of jewellery enclosing a photo, which probably is a memento of priceless and sentimental value. Jewellers are now including a far larger variety of photo jewellery in their stock than they have hitherto done, and the manufacturers also are devoting much more attention to the line. Send us the photo with particulars and we do the rest."

* We have found that paraphenylene diamine and orthoamidophenol are not the only developing substances which can produce deposits showing this special feature, and made up of very fine grains of reduced silver. We have obtained similar results with most developers under certain conditions, only less perfect than those obtained by the use of paraphenylene diamine and orthoamidophenol. We are endeavouring to determine precisely and to generalise the conditions relating to the formation of these deposits, having a special appearance, hoping to throw light on the theory of these phenomena.

AMERICAN NOTES AND NEWS.

THE ROTOGRAPH CO.—The Rotograph Co. has incorporated under the New York State laws, with a capital of \$300,000. Mr. Arthur Schwartz, president of the parent company in Germany, is the president of the American company. This company expects to put out many photographic novelties in the very near future, besides pushing their well-known brands of bromide paper.

WILLIAM H. RAU, the official photographer of the World's Fair, at St. Louis, has received notification from the French Government that he had been decorated with the "Palme Académiques." With this letter he received his diploma, signed by the French Ministry of Public Instruction and Fine Arts, which authorises him to wear the title and decoration of "Officier d'Académie."

A USEFUL HINT TO GUM WORKERS.—A correspondent of the "Photo Beacon" writes:—"To make a solution of gum by the ordinary method is, to say the least of it, rather a tedious operation. The mixture of gum and water requires frequent attention in the way of stirring, and, even then, several hours elapse before solution is effected. The chemist who requires his solution clean and fresh, proceeds in the following manner, which is practically automatic, and depends on the natural law that the denser liquid falls to the bottom. He takes the gum in two or three folds of fine muslin, and of this makes a bag. This he suspends in a cylindrical measure containing water, so that the gum shall be just below the surface of the liquid, the muslin bag being tied to a glass rod or pencil laid across the mouth of the measure. Solution proceeds rapidly. The foregoing method finds additional favour in the eyes of the chemist, as no heat is required, heat, in his opinion, causing a tendency to rancidity.

MR. HOWARD DU BOIS recently gave a talk to the Photographic Society of Philadelphia entitled "A Method of Accurately Colouring Lantern Slides." His talk was illustrated by a number of coloured slides of scenes in the Canadian Rocky Mountains. In colouring slides, he said that the great trouble arose from the lack of the colour note in photography, this depriving the colourist of proper data. The different methods employed by Ives, McDonough, and others were not perfect, being too complicated for ordinary use. He thought hand-colouring was much better. In the method of colouring devised by him he used celluloid strips, coated with gelatine, stained by aniline dyes of various colours. These strips were accurately matched against the picture on the ground glass, thus enabling his artist readily to select the proper colour. The principal point was to secure the proper gradations of greens. The result, he thought, was to be criticised not from an artistic, but from an effective standpoint. The English plates, the Paget, were good for the purpose. He had found the dry plate to give much better results than the wet. The making of slides of this kind was different from the making of slides for other purposes, no contrast being necessary, as this was supplied by the colouring.

THE FLASHLIGHT FIEND.—"Has it ever occurred to you," asked a New York photographer, "that the tintype artist, as he called himself, is passing out of business? Here and there you will find him, at a resort like Coney Island or Far Rockaway, and not long ago I found one in the vicinity of Grant's Tomb. But the tintype artist of the smaller country town is a memory. You ask what has become of him? Most of them, I think, have become itinerant flashlight artists. And for real battlefield nerve they are ahead of the Japanese soldiers. They will walk into an office with their outfit and an-

nounce that they have come to take a flash of the room, before the occupants realise it the apparatus is at work, flash is made, and the chaps who do it—there are generally of them—fold up their tripod and vanish. Then occupants of the room begin to wonder what it is for. They find out within a few days. One of itinerants returns with mounted pictures, which he offers for \$1 each. Strange to say, the people who have been flashed buy the product, but I am of the opinion they often do so to keep the pictures from being exhibited elsewhere. In other words, they buy up the circulation. A book agent or canvasser gets access to your office you show the door; but one of these strolling flashlight fiends can walk in upon you, distract you from your business, fill your room with smoke, walk out, come back in a week, and sell you what he calls a picture, and you submit as quietly as a young man who comes in contact with a nursing bottle. And the funny thing about it is that this chap comes to the city to do his business. You never find him in the country town."

"SUNNING DOWN."—Ninety per cent. of the amateurs using one or the other of the popular developing papers of course using some form of artificial light for printing. This reason it may seem a little out of place to use a word to describe a process involving "sunning" of the print, reminds me of the "St. Louis and Canadian Photographer." "Sunning down" was a well-known remedy with the older workers in print-out processes, particularly during albumen days. It was resorted to in correcting the snowy effects resulting from over-developed, under-timed negative. It is even more applicable to our gas-light papers than to those involving old assistance. An amateur came to me recently with a negative he desired to improve by reducing. Such a procedure is risky, entailing as it did a possible loss of the all too small detail. As the scene contained no real high lights I advised that he simply sun it down in printing. He failed to understand. I had all the material for printing close at hand so volunteered a demonstration. A straight print was made to determine the time required and proved the need of a remedy to overcome the harshness of the result. The first sheet of paper was exposed for the correct time, removed from the printing frame, and, holding it in my hand, I turned up the light for a second or two. It was then developed, and while hardly what one might call a perfect print, was much superior to the first. Neither did it have the same flat appearance one recognises as an indication of light-struck paper. The effect was entirely different, owing to the nature of the negative. Should there be necessary high lights in a print "sunned," it is not a hard matter to clear them up with a light reducer.

NEW AMERICAN STUDIO LIGHTING.—In equipping their new photograph gallery, Rojas and Connor, of New Orleans, I have departed completely from the established idea of fitting an operating room, and have established their plant on lines absolutely new in high-class photography. They have done away with the slanting skylight, considered before as absolutely necessary to secure the best results, and have installed a perpendicular light made of hammered glass, which gives the operator a horizontal in place of a slanting light. Mr. Rojas explaining the creation of this absolutely new feature of photograph gallery to the "Photographer," explained how he was struck on the idea which he developed. A number of amateur photographs were given him to print, which had remarkably fine lights, which had been taken in a room not to a window. The established idea is that only the light coming from 45 degrees down across the face and body gives the best

ults. He gave the matter a great deal of study, and decided that he could secure better results by letting the light strike the object at 45 degrees horizontal, for he would get rid of all shadows, which are matters of such bother to the operator. He experimented, and found that by making the skylight wide enough he could accomplish the desired results, and control the light as he saw fit by means of shades and curtains. When he moves into the present building he will put in a windowing up nearly the width of the room, and have hammered glass, which distributes the light perfectly, fitted perpendicular to the floor, like a wall of glass. At either side he put in windows, which could be opened for ventilation, and could be controlled by means of green shades. Then he papered the walls in dark green, and the ceiling in a light colour. The result was that he got results which were far beyond his expectations. The same light struck the subject from head to foot. There were no muddy shadows, no shadows under the eyebrows, nose, and the like. The effect was strikingly natural. The effect in taking fine draperies, especially light colours, was far ahead of the old system. There was none of the chalky effects and deep shadows, but in their place a soft light on the most exposed parts and a half-toned shadow, which did not even lose the material pictured. By constant experiments he has found that subjects can be taken with broad hats and there are no shadows under the hat itself, for the light strikes the hat on a line parallel with the earth. The new skylight he would make easy the fine effects in large groups of figures, and would allow him to take pictures which would reproduce the interior of a room effect, the ceiling being as much in view as the floor. Formerly that was out of the question, for the light came from aloft, and cut off any such deep picture. In fact, time illustrated to him that his sea had really revolutionised all the established rules, and would time revolutionise the system of fine photography itself.

The summer number of "Country Life," of which we have just seen a copy, is undoubtedly a first-class production, containing many beautiful photographs by well-known photographers. These pictures, as samples of good half-tone, tone, and superior printing, would be probably hard to beat. The literary contributions are also of a high standard.

GENERAL Staff Outing of Houghton's Ltd. Saturday, July 2, was served as a closed day at 86 and 89, High Holborn, and 97, Hatton Garden, in order that the entire office and warehouse staffs might have the opportunity of spending an enjoyable day's relaxation from the pressure of the season's business. A full series of sports was organised by a specially selected Sports' Committee, and held at the Crown Hotel Athletic Grounds, Broxbourne, a charming spot on the banks of the River Lee. Early access from London was made in special saloons from Liverpool Street Station at 9.29 a.m., and on arrival, a cricket match was arranged Married v. Single, which remained a draw at 12 o'clock, when the principal work of the day was commenced in a well contested tug of war, which was ultimately won in a final heat by the representatives of the clerical staff. Following on this, the four heats of 100 yards' contest were run. At the 6 o'clock the all-important lunch was served to over 190 employees, presided over by Mr. G. Houghton. In a few well-chosen words, Mr. Houghton welcomed his staff, and referred to the many years a number of them had been directly associated with him, and his heartfelt remarks went home to all present. At the conclusion, he was appropriately acknowledged with loud cheers, and a response was made by Mr. Wilcox, but as this was not a day for long speech-making, it was unanimously decided to again return to the field of sport, where an excellent programme of events was carried out with enthusiasm. During tea Mr. E. W. Houghton announced that the directors desired to make the outing an annual affair. The Tudor and Ilex Works staffs had their outing independently some weeks ago.

" TAKEN, FINISHED, AND DELIVERED IN TEN MINUTES."

ABOUT two years ago I received a printed invitation from a local department store to have my picture taken there, the ad. stating that it would take but ten minutes to do the trick and deliver the finished picture—I beg pardon, I mean product. Being rather curious to see how this could be done I called upon a friend who was manager of the amateur photographic department in the store. Through his influence I was permitted to examine the "works." I found that the pictures were not tints, but actual black and white prints upon postal cards—Rotograph post-cards, as it happened. The two operators were Germans, most kind, but very secretive about their process, and I could gain no information regarding it except what I could see outside the dark room. This part of the process was simple, so far as I could see. A plate-holder was inserted in the camera, the sitter placed in a chair under a skylight, and exposure made in the usual manner, and then one of the operators would whisk the plate-holder away to the dark room, from which he would presently emerge with the finished product.

Just before these operators left town I had an opportunity to see how all this mysterious manipulation was accomplished, although I had guessed their method even before I saw it. The scheme necessitated the use of a box similar to an enlarging camera. Sketch of similar apparatus is shown herewith. The plate, which, by the way, was a $3\frac{1}{4}$ by $4\frac{1}{4}$ in a 5 by 7

camera, was taken from the plate-holder and developed, a strong, rapid-working metol-hydrochinon developer being used, rinsed, and placed in an almost saturated acid hypo solution. Fixing took but two or three minutes, and then the plate was rinsed again and swabbed off with a tuft of cotton. It was then placed in the box—wet. Before going any further it will be necessary to describe the apparatus.

The box is to be made as shown, the dimensions being about 24 in. long, 8 in. wide, and 10 in. high, inside. The negative end of the box is open, while the other end holds the sensitive paper, and is provided with a door the full size of the opening. At the negative end four cleats are nailed inside the box to form a groove, into which an 8 by 10 kit may be slipped. This kit may have an opening suiting the plate to be used. A kit can be easily made at home, if the expense be an item. Midway of the box, inside of it, a slide should be rigged up provided with a board to hold the lens used for projecting. This lens may be your camera lens, or a cheap single achromatic. A piece of celluloid may be tacked to the bottom of the box marked with numerals to aid in securing the size of picture desired upon the sensitive surface at the other end. Illumination of the negative for projection may be secured by placing the negative end of the box against an opening, which has been provided in a window-frame, or, what is more desirable, a pair of condensers mounted in a separate box, with an artificial light of some sort behind them, may be used. The latter is the method used by the two Ger-

man operators. Having placed the wet negative in the kit, a piece of 8 by 10 ground glass may be placed at the closed end of the box, the door being swung open while the image is focussed. When a sharp image is secured, of the size desired, a piece of bromide paper is inserted and the exposure made, the print developed, fixed, and rinsed. The developer and fixing solution are similar to those used for developing the plate—very strong. A hypo eliminator of some kind was used by the operators, the print again rinsed, dried quickly (with the aid of heat if necessary), trimmed, and delivered. This would apparently take some time to do, but the operators were so expert that it was all done quicker than I could explain it, and the prints were often delivered in ten or twelve minutes. To facilitate matters, the lens in the projecting box was set at a certain point, and as all plates and resulting images were alike in size, there was no need for focussing. In fact, with the negative always in the same place at the end of the box, the sensitive paper at the other extreme end and the lens exactly in the centre between the two, the image will always be sharp and the size of the picture the same—that is, natural size of image on negative. If a larger or smaller image be desired, provision must be made to move the negative as well as the lens. This could be done by mounting the kit in a slide similar to the lens slide.

How permanent these pictures were I have no means of knowing, as I have not kept those I had taken, but I should judge they were fairly permanent. The above method would be of doubtful value to the amateur unless he would care to start in this business himself, but inasmuch as the arrangement can be used to make enlargements, and also quick proofs from wet negatives, it is worth looking into. A proof can be made from a wet negative in quicker time than it takes to tell it, and the results are always better than by placing a sheet of wet bromide paper in contact with the wet negative and printing in the frame. I built one of these boxes about a year ago, and used it in connection with newspaper photography, in which I was then engaged, and I had them all beaten when it came to turning out fast work, and there was no necessity of using a plate larger than $3\frac{1}{2}$ by $4\frac{1}{2}$, whereas my rivals were obliged to use 5 by 7 cameras to secure the desired results.

BERNARD C. ROLOFF, in "Camera Craft."

LUCIO MAURICE HACKETT, late photographer, of Dale Street and Lime Street, Liverpool, appeared for his adjourned public examination at the Liverpool Bankruptcy Court before the Registrar. He admitted that his drawings recently had been at the rate of about £1,000 a year, but he explained that he had included in his drawings about £100 he had paid on account of the hired furniture. He also admitted that when pressed for money he had been obliged to sell stock below cost price. The examination was ordered to be closed.

THE Mammoth Pictorial Postcards.—The London Stereoscopic Company, of 54, Cheapside, London, E.C., have, we imagine, broken the record in the way of large-sized pictorial postcards. Admirably printed in colotype, they have submitted to us a series of 12 by 10 portraits of popular actresses, which can be sent through the post as ordinary cards. They are certainly very striking productions, and, as we have proved by experiment and observation, are immensely popular with devotees of that great modern cult, picture postcard collecting. But the company by no means confine their adaptation of the colotype process to mammoth cards. They produce cards of the ordinary size in remarkable variety, and also work the process for scrap views, facsimile reproductions, show-cards, book illustrations, trade catalogues, calendars, etc. We can recommend our readers to apply to the company for specimens in the assurance that there will be no disappointment with the quality of their very beautiful examples of photo-mechanical printing.

METHODS OF EXAMINING AND DETECTING THE COMPOSITION OF PAPER.

SINCE the introduction of various forms of gum bichrom printing the number of amateur photographers who prepare their own printing paper is increasing. Although innumerable pages of instructions have been written on the choice and use of the chemicals and pigments necessary for the purpose, selection of the most suitable samples of paper to receive sensitive film, and, subsequently the photographic image, received little or no attention.

At the present time the composition of the paper that is to be utilised for carbon or gum printing is a matter of the greatest importance, owing to the general use of paper manufactured from wood pulp. Some years ago the substance of all best class paper consisted of linen, cotton, or esparto grass; but these materials are now rapidly being superseded by pinewood, and even the more expensive papers often contain a large percentage of wood pulp.

Fig. 1.—Photograph of Various Papers After Exposure to Light and Air.

Paper made from wood has the objectionable characteristic of changing to a yellowish brown tint when exposed to light and air. This discolouration may proceed slowly or rapidly according to the conditions of storage, but the change is inevitable, and is merely a question of time. It is evident that the colouring tendency of this class of paper makes it a most undesirable material for photographic purposes, and carbon workers who wish to preserve the purity of the high lights in their pictures will do well to avoid the use of wood paper for the final support of their films.

The prejudicial effect of wood paper on pictures is experienced by artists, who are often supplied with card and paper made partly or wholly of wood pulp. In consequence a careful executed wash or chalk drawing, in which the whites of the picture are, or ought to be, supplied by the surface of the card board, becomes in a few months degraded in tone, through the wood pulp paper turning a dingy yellow.

The writer has met with several examples of this discolouration in valuable drawings which had been prepared for reproduction. When the pictures were first submitted, the lights were practically pure white, but when the same pictures were sent up a few months later for reproduction, the appearance of the sketches was altogether changed. In one case the artist had painted in the whites of the picture before a satisfactory reproduction could be obtained.

When the appearance of a photograph has been marred in any manner the only way to remedy the defect is to take another negative, that is, if the photographer is fortunate enough to possess the original negative, but in many cases where the plate has been overexposed or lost, this is impossible.

Fig. 2.—Photo-micrograph of Paper Manufactured from Wood. Stained with Phloroglucin. $\frac{3}{8}$ in. obj.

Fig. 1 gives the result of comparative tests made with various papers in order to observe the result of exposing paper made of different materials to light, air, and damp.

As will be seen in the illustration, three fragments of paper made of wood, esparto, and rag respectively were pasted on a card

Fig. 3.—Photo-micrograph of Paper made from Rags. $\frac{3}{8}$ in. obj.

and exposed in the open air for six days. Light in the absence of moisture has considerably less effect on the colour of paper, the weather being fine at the time the experiment was made, very little discoloration was observable at the end of three days. The papers were then dipped in water about twice a day

and exposed to light in a moist condition. This soon effected a change in the paper made from wood, and it rapidly began to darken. The papers were photographed after six days' exposure. The sample of rag paper was as white as when first exposed, the esparto sample had become very slightly darker in

Fig. 4.—Photo-micrograph of Esparto Paper. $\frac{3}{8}$ in. obj.

tone, while the wood paper was a dingy yellow colour. For the purposes of comparison a fresh piece of the same sample was placed beneath the exposed portion of wood paper before the card was photographed for reproduction.

This experiment clearly shows the most suitable kinds of paper for photographic purposes.

Fig. 5.—Paper composed of wood and rag fibres. Dark parts show wood stained with Phloroglucin. $\frac{3}{8}$ in. obj.

Rag paper is, of course, the best, but is also the most expensive. Paper made from esparto grass, as it is only slightly affected by light and air, is also a suitable material; but for pictures to which any value is attached, wood paper ought never to be used.

Paper often consists of a mixture of rag or esparto, with a certain amount of wood pulp; this class of paper is better than that which is manufactured solely from wood, but is at best only a partial improvement.

There are several means of detecting the presence of wood pulp in paper. Some of the methods require the use of a microscope and a certain amount of experience in working it; but there are certain specific stains which readily demonstrate to the unaided eye the existence of wood pulp when it is present in a fairly large proportion.

There is a considerable difference in the structure of wood fibres from those of linen, cotton, or esparto grass. When paper is examined under the microscope wood fibres can generally be distinguished even if they have not been stained. A low power, about $\frac{2}{3}$ in., is a convenient lens for the purpose. A typical feature of wood fibre is found in a ladder-like arrangement of fibres which is not found in rag or esparto paper. These parallel lines are plainly seen in Fig. 1. The fibres are coarse, flat, and irregular in shape. Esparto fibres are thin, elongated, and regular, somewhat resembling those of linen and cotton.

The best method of distinguishing the fibres of paper is to immerse the substance in selective stains. For wood fibres the most reliable and simplest stain is phloroglucin. The chief drawback to the use of this reagent is its high price (one ounce costs about 16s.), but only a very small quantity need be purchased. Phloroglucin used in conjunction with hydrochloric acid stains ligneous tissue a bright-red colour.

The following formula will be found convenient and reliable:—

Phloroglucin5 gramme.
Absolute alcohol	10 CCs.
Distilled water.....	40 CCs.

A small quantity of the solution is poured into a watch-glass, and a portion of the paper to be treated is placed in it for about ten or fifteen minutes. The paper is then transferred to another glass and treated with a few drops of strong hydrochloric acid.

If the paper is made from wood pulp it immediately assumes a bright red colour, while rag or esparto papers are unaffected. In making a trial of this stain, a piece of paper from one of the daily newspapers can be used, as these are all printed on paper made from pine-wood.

Hydrochloric acid is sometimes mixed with the phloroglucin solution, and the staining is finished in a single operation. The red stain is, of course, less pronounced when the paper is only partially composed of wood. There is another method of staining that can be used to identify the various fibres. This consists of chloride of zinc and iodine. The following formula can be recommended:—

Zinc chloride saturated solution	35 CCs.
Pot. iodide	5 grammes.
Iodine1 gramme.
Water	10 CCs.

Unlike phloroglucin this stain acts chiefly on linen, cotton, and esparto fibres, staining them with a violet or blue tone, merely imparting a yellowish tinge to wood paper. The rag fibres are stained almost immediately, but wood generally requires a prolonged immersion before a pronounced yellow stain is produced.

Fig. II is a reproduction of a photo-micrograph of wood paper; the irregular fibres and parallel lines are very noticeable.

Fig. III. shows a photograph of linen paper, the fibres being very different from those shown in Fig. II.

Esparto paper fibres are shown in Fig. IV.

Fig. V. is from paper composed of both wood and rag; the dark parts of the photograph show where phloroglucin has stained the wood fibres red.

There remains the question as to whether some means can not be devised to prevent the objectional discolouration of paper made from wood pulp. At present there is no method of overcoming this defect, and little or no effort is made to find a cure, though it seems well within the bounds of possibility. In a dry, dark place, wood paper will keep well, but light, air and damp soon play havoc with its colour.

J. I. Pigg, F.R.M.S.

FORTHCOMING EXHIBITIONS.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Secretary, W. Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. M. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. sec., H. C. Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

1905.—Northern Photographic Exhibition. Secretary, F. G. 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 1.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. An Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve weeks. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 lantern slides and prints made with Barnet products. Elliott Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Patent News.

The following applications for patents were made between June 27 and July 2, 1904:—

Cameras.—No. 14,458. "Improvements in reflector hand cameras." Samuel Dunseith McKellen.

Cameras.—No. 14,590. "Improvements in photographic hand cameras." Alfred Sidney Spratt.

Shutters.—No. 14,683. "Improvements in roller blind shutters for photographic cameras." (Date applied for under Patents Act, 1901, 17th July, 1903, being date of application in Germany.) Complete specification. Neils Marius Knudsen.

Cameras.—No. 14,824. "Improvements in photographic cameras." Owen Linley.

Appliances.—No. 14,850. "Improvements in photographic appliances." Henry Charles Braun.

Cameras.—No. 14,854. "Improvements in photographic cameras." Charles Howell and George Lloyd Moore, trading as the Midland Camera Company.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July	Name of Society.	Subject.
.....	South London Photo. Society...	Wet Collodion Process. Mr. W. T. Wilkinson.
.....	Bowes Pk. and District Ph. Soc.	Competition. Outing Prints.
.....	Nelson Photographic Society...	1. Self-toning Paget F.O.P. 2. Sepia Platinotype. Mr. J. Emmott.
.....	North Middlesex Photo. Soc.	Colour Filters and Isochromatic Plates. Mr. J. McIntosh.
.....	The Optical Society	Binocular Vision and the Theory of the Stereoscope. Mr. T. W. Barber, M.Inst.C.E.

News and Notes.

ISWICH Camera Club.—Through unforeseen circumstances this club has had to alter the dates of their annual exhibition, from November 15 and 16, as announced, to Tuesday and Wednesday, November 22 and 23. The schedules will be circulated shortly.

THE Brooks-Watson Daylight Camera Company, Ltd., inform us that owing to the success of the "Rajar" manufactures, they have opened showrooms and offices in London, at 119, High Holborn, W.C., corner of Southampton Row, and that their productions can now be seen there.

WE have received several of the admirably printed guide books published by the Health Resorts Development Association, of 2, Gray's Inn Road, High Holborn. These guides are well illustrated and contain a fund of information that should be of use to the photographer visiting the districts dealt with. The latest is of Bexhill, and, like the previous volumes, will be sent free on receipt of a postcard.

A SECOND edition of "Photo-Printing," by Hector Maclean, F.R.P.S., is to hand. The book, which has proved its worth in the past as a reliable guide to photographic printing methods, has, in the new edition, been revised, condensed, and considerably added to. Working instructions and many new formulae relating to the newer printing papers have also been included.

WALKER Art Gallery Curatorship.—The Liverpool City Council at a meeting last week unanimously confirmed the recommendation of the Library, Museum, and Arts Committee appointing Mr. Edward Rimbault Dibdin, Curator of the Walker Art Gallery, at a salary of £400 per annum. Mr. Dibdin is a Liverpool man, and is well known in photographic and art circles in that city.

SOUTHAMPTON Camera Club.—At a meeting of the members of this club on the 11th inst., under the presidency of Mr. G. T. Vivian, a demonstration was given by Mr. A. E. Henley on development with imogen sulphite, and its value with plates and papers was ably described. A very useful paper on "Fixation" was also read by Mr. Vials, who unfolded the merits and demerits of both the alkaline and acid baths.

ART in Whitechapel.—At the Whitechapel Art Galleries there will be on view until July 18 an exhibition of amateur and art students' work. The object of the display is that of showing to the East End what others, not themselves professional artists, are capable of doing, in the hope that it may inspire greater efforts in pictorial art. Almost all the leading sketch clubs have supported the project, sending in collective groups of their members' work.

WE regret to have to record the death of John Freeman Edward Davaston, of West Felton and Davaston, Shropshire. Mr. Davaston's pictorial work in photography about five or six years ago was well known and justly admired. His novel and unconventional views of St. Paul's, etc., some of which were published in photogravure, will be long remembered. He died at Fanley Parade, West Hampstead, at the age of 51.

THE Hull Photographic Society had a successful outing last Saturday to Ferriby and Welton. The marine subjects at the former attracted a few, whilst the tree studies and Dale at the latter seemed to be appreciated by others, from the fact that anything photographic in the shade proved more pleasant owing to the heat of the sun. There was not much serious work attempted until after tea. The next outing is to Ripon, for Fountains Abbey, July 23.

COPYRIGHT laws extend to the phonograph if a Brussels Court has rightly interpreted international jurisprudence on this subject. M. Sardou brought an action against a cinematograph concern for allowing their phonograph to repeat a part of "Madame Sans Gêne." At the same time M. Puccini asked for redress on the ground that they had played, photographically, some airs from the "Vie de Bohème." An Appeal Court has decided in favour of M. Sardou's claim. It rejected that of M. Puccini, but on the ground that the music sent out by the

phonograph was not meant for the "Vie de Bohême," but for the "Cavalleria Rusticana."

X-RAYS Again.—Already the X-rays have been utilised for a variety of purposes, and now it is stated in the "Globe" that the manufacturers of that imitation antique furniture which finds such a ready sale have pressed it into their service. Formerly the suggestion of worm-eaten age was given by boring fine holes, and now the genuine bacteria which attack wood are, it is declared, first cultivated in potatoes, and afterwards rubbed into the "antique" furniture. When they have sufficiently suggested the process of decay and it becomes desirable to kill the bacteria, they are subjected to the action of the X-rays, and death supervenes.

THE Optical Society.—The fifth annual dinner of the Optical Society will be held at the Mitre Hotel, Hampton Court, on Thursday, the 21st instant, at 6.30 p.m. By the courtesy of the Director of the National Physical Laboratory, Bushey House, Teddington, Dr. R. T. Glazebrook, M.A., F.R.S., arrangements have been made whereby members of the Society and their friends attending the dinner will have the privilege of visiting that institution in the afternoon of the day named. Application for tickets should be made without delay to the hon. secretary, W. Salt, 20, Hanover Square, London, W., who will supply all particulars.

PROPOSED New Poisons Act of South Australia.—A deputation from the Pharmaceutical Society of South Australia recently waited on the Chief Secretary of the Colony, and pointed out to him that the 1862 Poisons Act did not in any way serve the requirements of the present time. Since January, 1902, there had been thirty-two deaths through poison, ten of these being accidental, and the remaining twenty-two cases of suicide. What the deputation desired was that the Society should administer the Act, and should be empowered to impose an annual licence fee on each individual entitled to sell poisons. A Bill, which has been prepared by the Society, will probably be presented to Parliament at an early date.

AN International Industrial Exhibition will be opened at Cape Town in November, 1904, and remain open for a period of three months. The Government of the Colony intend to make a comprehensive official exhibit of local products. Photography, optical goods, and scientific instruments are specially named, and extensive exhibits have been arranged for by prominent firms of France, Germany, Austria, Holland, etc. The exhibition grounds will be constituted a "bonded store," and any duty paid on goods not sold will be refunded on their reshipment. Further particulars can be obtained on application to the Trades, Markets, and Exhibitions, Limited, Palmerston House, Old Broad Street, E.C.

SPAIN has a long leeway to make up in science, but a more fruitful hour is at hand. She has just established, for instance, the first observatory, which is to be devoted entirely to the elucidation of the connection between changes in the sun's surface and changes in the magnetic and climatic conditions of the earth. It is now pretty generally admitted that if we want to understand terrestrial weather we must study the solar weather which determines it. This piece of Spanish enterprise will, no doubt, be much appreciated by the snapshotting Don, and the Spanish equivalent for our photographic societies, who will doubtless now sally forth armed not only with cameras, but with the knowledge that the weather and sunshine are guaranteed by the Government.

THE death of the widow of the late D. O. Hill, on the 5th inst., at Edinburgh, recalls to memory her husband's contributions to photographic art. Mr. Hill in his day was secretary to the Royal Scottish Academy, and his attention was first directed to photography through the difficulties he encountered in painting his 1845 Disruption commemorative picture. This painting includes about 470 portraits of ministers, elders, and others, and the work entailed, as might be expected, was stupendous. His work, however, was greatly simplified when Mr. Hill employed photography as a medium for making his preliminary studies of the many characters depicted. The gain to photography was well shown in the fine collection of his photographic portraits exhibited at the recent Scottish Salon.

THE delightful promise of this year—let us hope it will be kept—will double the best country thing of the year, which is long grass full of flowers and sorrel, with the hay harvest that follows. For once the fields are shaven, the greatest beauty of colour and surface is gone for another twelvemonth. This happy year we hope to see it twice, and to have the hayfields, so delightful during the past fortnight, repeated in August, and although it appears to be the fashion to sneer at the everlasting haymaking scene as portrayed by the camera, the sunbonnetted damsels, in graceful attitudes, hay-rake in hand, sturdy waggons, and top-heavy haycarts, with their overflowing burden, we venture to think the fault is more to be found in the individual with the camera than with the material at hand for picture making.

THE medallion by Mr. Hamo Thornycroft, placed in the north aisle of the choir of Westminster Abbey to the memory of Sir George Stokes was unveiled on Thursday last by the Duke of Devonshire, Chancellor of Cambridge University, after a crowded meeting in the Jerusalem Chamber, where the attendance included the Dean of Westminster, who presided, Mr. Choate, the United States Ambassador, Lord Kelvin, Lord Rayleigh, Sir John Gorst, Sir James Dewar, Sir Richard Jebb, Sir William Huggins, President of the Royal Society, the Rev. Canon Duckworth, Bishop Welldon, Sir Frederick Bridge, the Rev. Canon Beeching, the Rev. Canon Henson, Professor Larmor, Professor Forsyth, the Master of Trinity College, Cambridge, and the Dean of Christ Church, Oxford. Sir William Huggins, the Rev. F. H. Chase, Vice-Chancellor of Cambridge University, Lord Rayleigh, and Lord Kelvin spoke eloquently of Sir George Stokes's position in the front rank of scientific men.

THE Magic Lantern in Church.—At the Church of St. Mary-at-Hill the service is punctuated with photographic pictures thrown on the screen. The words of the service are also projected by the lantern, and the choir sing to the accompaniment of brass and drums, with the Rev. W. Carlisle leading "the chorus" from the pulpit, and blowing such notes as are within reach of his cornet-à-piston. All the time the succession of pictures and printed words is proceeding. The Creed is recited slowly to an organ accompaniment, and each article of belief—even the Communion of Saints—is illustrated with a click from the machine up in the organ loft. It is doubtful whether such means will find the beliefs of the average church-goer better defined or strengthened, but the fact remains that, while church after church throughout the city on Sunday ring out their invitations in vain, the Church Army fills this particular church on a broiling July evening with the help of its peculiar methods and the magic lantern.

PHOTOGRAPHY at Oxford.—The veto placed upon the use of cameras in many of the colleges in this university and in public and semi-public institutions throughout the country, is becoming a greater farce every day, says the "Oxford Times." While the Oxford man is given to understand that photography is only allowed with special permission from the college authorities, and has his ardour dampened by the necessity of writing to them individually, the American visitor, with characteristic audacity, not entirely due to ignorance of the regulations, calmly walks in with his hand camera, sometimes folded up and secreted, at others well exposed to view, and secures the requisite snapshot. As might be guessed, the introduction of the collapsible roll-film variety of camera is responsible for much of this poaching, for, as the college porter naturally refrains from acting with the authority of the customs' official, those with the most liberal allowance of impudence and the least regard for dons and the decrees of dons, secure the greater number of interesting photographs.

BIRMINGHAM Photographic Society's Garden Party.—About one hundred members and friends of the Birmingham Photographic Society were entertained on Saturday, July 2, by the President (Mr. A. J. Leeson), and Mrs. Leeson, at a garden party at their residence, Barnt Green. After formal reception of the guests, Mrs. Leeson was presented with a bouquet, and games were then indulged in, including tennis, croquet, and a putting competition. Instrumental music was played at intervals. Considerable interest was evinced in a number of competitions in photography for members. The subjects were living models, and this is regarded as a novel, if not unique, kind of competition for the Society. There were four groups,

isting of a dairymaid and a cow in the East Wood, a group at well in the costume of George III., a simular group at a sundial, a genuine countryman in the West Wood. Some fifty members part in the competitions, and about 200 plates were exposed. dairymaid and the cow seemed to be the most popular subject.

Edinburgh Stereoscopic Atlas of Anatomy.—Messrs. Jack, of burgh and London, announce the publication of a complete s of anatomical photographs for the stereoscope, so arranged as exhibit the natural relations of the parts. The photographs have taken from special dissections prepared by the aid of formalin, the work of preparing them has been carried on in the anatomical rtment of Edinburgh University, with the permission of Proor D. J. Cunningham and under the supervision of the senior onstrator of anatomy, Dr. Waterston, by whom the series is g edited. The photographs are of the usual size for the stereo- e, and each one is mounted on the lower part of a card measuring y 7in., the upper part of which is reserved for descriptive press. The specimen photographs sent are of exceptionally fine ty, and the stereoscopic effect is excellently produced, affording best possible imitation of real structures. The series will com- 250 separate stereographs, and will be issued in sections of t 50 each, contained in suitable cases, at a price for the whole s of £6 5s., including a stereoscope. The first section is ised during the autumn, and the publishers hope to complete work early in 1905.

Latest about the N-Rays.—It is known that the N-rays are e undulations of the ether similar to those of light, but M. Becquerel now thinks that these rays may also provoke or ate a transference of material particles from the body emitting . He finds by experiment that when the rays traverse a mag- field, even of slight strength, perpendicularly to the lines of etic force, they do not produce any change in the brightness e phosphorescent sulphide of calcium, whereas when they cross ame field parallel to the lines of force they do. He also ob- d that the strongly radio-active bromide of radium and a salt amium feebly radio-active produce an effect on the sulphide of cal- similar to that of the N-rays. M. Sutton finds that the colour feeble source of light has an influence on its sensibility to the n of N-rays. Blue or violet sources are more easily increased ightness by the N-rays falling on them than are green rays, and w, orange, or red sources appear to remain unaffected by the . Another interesting fact is that N-rays increase the sensibility e eye for violet, but not for red light. A visible spectrum in rk room when acted on by N-rays appears to lengthen towards ultra-violet or invisible rays. The sensibility of phosphorescent ances to N-rays is also very variable with their colour. The ide of calcium, with a violet phosphorescence, is the most sensi- Alkaline-earth sulphides and zinc sulphides with green phos- esences are less sensitive, and M. Sutton has not observed any t of the rays on zinc and alkaline-earth sulphides with orange phos- esences.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject e approval of the Publishers, and advertisements are inserted tely without condition, expressed or implied, as to what appears in at portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

Answers to Correspondents.

- *¹ All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *² Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *³ Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *⁴ For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

John Alfred Horsburgh, 4, West Maitland Street, Edinburgh. Photograph of the Rt. Hon. Sir Robert Cranston, the Lord Provost of Edinburgh, Standing in his robes.
Mrs. Caroline Gavin, 83, St. Giles, Norwich. Photograph of Group of Provincial Grand Masonic Lodge of Norfolk.
John George Gowland, Photographer, Church Street, Crook. Photograph of the late Thomas Wilkinson.
John William Powell, 29, Hannah Street, Porth, Glam. Photograph of Rev. William Edward Prince.
Charles Alfred Brett, Photographer, 1, Avenue Road, Hampton, Middlesex. Six Photographs of the Reverend Prebendary Raim. View and Rural Dean of Hampton, Middlesex. Four in his robes, and Two in Ordinary Clerical Dress.
Arthur May Cormack 31, Newborough, Scarborough. Photograph of Group of Tom Currier's White Musketeers.
Samuel Nixon of Glenvista, Oregon, Londonderry, Ireland. Photograph of Mrs. Kerrigans Sitting Beside her Spinning Wheel. Mrs. Kerrigans was visited by the King and Queen near Leenane, Co. Galway, Ireland, during their visit to Ireland in the year 1901.

F. FRENCH.—We have nothing of the sort you require.

OPINION WANTED.—"PRINTS" says: "I shall be much obliged if you will kindly give me your opinion of my retouching from prints enclosed." In reply: Our opinion is that the work is poor—very poor indeed.

"OPERATOR."—A reference to the Almanac will give you all the information you require re accessories. Firms such as Marion's, Soho Square, W.C., or Fallowfield, Charing Cross Road, W.C., will supply what you require.

VIEW ANGLES.—L. M. asks: "How am I to go about ascertaining what angle a particular lens includes upon plates of various sizes?" In reply: If our correspondent refers to pages 1161-2 of the "Almanac" he will find an article on the subject. It is too long to be dealt with in this column.

COPYRIGHT.—"ONE IN DOUBT" says: "I should esteem it a favour if you would answer me the following question: Is it legal or not to print postcards and offer them for sale from a sitter's negative that they have bought photographs of, without the consent of the sitter?" In reply: Certainly it is illegal, if the sitter paid for the portraits in the first instance.

BURNISHER.—"J. G." writes: "I will esteem it a favour if you will tell me which is the best way for a hot roller burnisher to work—whether the rollers should both run the same speed, or is it better for the hot one to run quicker, and, if so, how much quicker?" In reply: Roller burnishers as sent out by the makers are geared so that the rollers work to the best advantage. Why do you wish to make any alteration?

ZINC TANKS.—WASHER says: "I have been using zinc tanks for print washing, and to prevent the metal acting on the prints have coated the insides of the tanks with enamel. This is rather costly and requires frequent renewal. Would ordinary Brunswick black be quite suitable? Or would you recommend heating and coating with pitch and resin?" In reply: For zinc there is nothing better than enamel. Brunswick black, pitch, and the like are better adapted for wooden tanks. If the zinc is well cleaned a good enamel should be fairly durable.

VARIOUS QUERIES.—"OLD READER" asks: "(1) Could you name me any firm of opticians who make the small, cheap lenses for toy cameras which are sold for about 6d. each? (2) I have orders occasionally for presentation portraits. Can you name me any

firm who makes small brass plates, with inscriptions on them, to put on bottom of frames? (3) What is best thing for polishing brass mounts of lens to make them highly burnished?" In reply: (1) We cannot. Indeed, we have seen no sixpenny cameras that have been fitted with lenses. (2) Any engraver that engraves the inscription will also provide the plates. (3) Lens mounts are lacquered. Your best plan will be to send the lens to an optician to be relacquered.

REDUCING BROMIDE PRINTS.—R. ROBERTSON asks: "Can you tell me of a safe reducer for over-developed bromide prints that will not affect the colour or permanence of the prints?" In reply: There are several reducers that may be employed, such as this, carbamide 20 grs., citric acid 10 grs., water 10 oz., or hypo 1 oz., water 5 oz., potass ferricyanide 10 grs., or the ammonium persulphate reducer, but the colour will to some extent be altered. There is also the potass cyanide and iodine reducer, but as this is a dangerous poison, it can hardly be regarded as a "safe" formula. The simplest thing is to throw the prints away and make fresh. It is the more economical in the end, if time be of any value.

SPOTTY PRINTS.—For some time I have been troubled with small spots on my finished prints, and have been at considerable trouble trying to trace the cause. I find that when fixed in a sample of hypo usually sold I get none of them, but with this particular sample I am troubled with them. The shape of the crystal seems unusual; also the fact that some of the crystals are white. I am sending you herewith a sample of the soda and a portion of photo showing the spots mentioned. As I have rather a large quantity (2 cwt.), I should be glad if you could say what is the fault, so that I may complain to the firm who sent it and have it changed." In reply: We should certainly not suspect the hypo (the sample sent) as being the cause of the spots. The crystals seem all right. We think you must trace the spots to another source. As regards the white crystals, see last week's B.J.P., p. 602, "Iodine and Hypo."

STUDIO QUERY.—MARTIN says: "Will you kindly advise on the following? I have opened a studio on ground floor, with only a window at the front 7 ft. wide and from ceiling to within 2 ft. of the floor. The room is 20 ft. by 7 ft. I have fixed a light with five incandescent lights attached, which I use on the right hand of the studio, and about 5 ft. from background. I am at present only doing stamp and midget photos, and bring the sitter almost close under the light. I submit some specimens for your opinion as to whether my light is not strong enough or whether my background is too dark. I give about three seconds' exposure. I also wish to take cabinets and carte-de-visites. Is my room big enough? What focus lens ought I to get and is my light strong enough?" In reply: The specimens sent are all under-exposed. The room is very small for professional work, and for full-length cabinets you will save to employ a lens of about 8 in. focus. Had you sent a plan of the studio we could possibly have advised you further.

UNSATISFACTORY BUSINESS.—H. P. U. writes as under: "I notice a correspondent in this week's 'B. J.' asks a question re unexecuted order (page 620). I sent for a sample of paper and enclosed stamps, and also had the same reply, so no doubt it is the same firm. Have not heard from them since. In June, 1901, a gentleman called on me saying he was a journalist, and wished to write an article on my business to be published in 'The Age' or 'Seymour's Journal,' and undertook to send me 50 copies of same for £1 1s. I paid him the amount, and on the following September he writes to say the articles are written and in type for this district, but has omitted mine until the next issue. I have received no copies, and cannot get a reply from him, though I have written several times. Can I sue him in the County Court for the return of my guinea? He gave his name as Dr. —." In reply: Certainly you can sue the man in the County Court, if you can find him. Possibly you might take stronger measures; but we are afraid you have lost your guinea.

PHOTOGRAPHING BUILDING.—FOCUS says: "I have to photograph a public erection at night when illuminated. Will you please

answer me the following questions as a guide for taking photograph?—(1) If I use a 'Busch Rapid Aplanat No. 3 Lens,' focus 10 in. stop 22, and Iso instantaneous plates, exposure would be about right, picture to be 1-1 plate? (2) illumination is done by electric lights—red, blue, and Should backed plates be all right, or ought I to use coated? (3) Is there any special method of taking these, ular subjects? (4) Is it best to work when quite dark, a slight amount of light better to help with detail of built? (5) Can you give any advice other than asked in the questions?" In reply: (1 and 2) How is it possible to ask such questions as these without knowing anything of the of the lights? Backed plates should certainly be used No. (4) Under some conditions, yes, it may be. (5) Make or two trial exposures, then you cannot go far wrong. not that occur to you?

VARIOUS QUESTIONS.—"BOB" asks: "Would you kindly tell (1) The best and most permanent method of making water large wooden dishes, bottoms of glass. (2) What dish will a $\frac{1}{2}$ pl. negative be from the enlarging easel 30 by 24 enlargement, using an 8-in. focus R.R. lens, with condensers? (3) Does a name block have to be heated blocking mounts in gold or silver?" In reply: (1) There is no very satisfactory way of making large wooden trays glass bottoms thoroughly watertight. Try painting the with a mixture of pitch with a little tallow added. The tallowing method has also been recommended for waterproof large dishes: Mix equal parts of gutta-percha and paraffin over a slow fire and apply while hot by warming the pouring some of the mixture inside and allowing it to flow from side to side. A warm iron passed over the surface will give a polished surface much resembling that in rubber after vulcanising. The coating is absolutely waterproof and will resist the ordinary acids and alkalis used by the photographer. (2) If you refer to page 1,159 of the "Album," you will find a table which will give you the distances required for any degree of enlargement, for any focus lens. (3) it is better heated.

VARIOUS QUERIES.—J. S. ADAMSON asks: "Can you inform me of good reliable books on the following subjects: (1) Painting with oils and water colours and pastel, photos and miniatures. (2) Finishing enlargements in monochrome. (3) Colodion chemistry, printing and toning. (4) On photographic optics. I desire to make a special study of optics, merely a describing the various lenses in general use by professional photographers. (5) What are per cent. solutions; how are they calculated? (6) What sort of hand camera (or stand) is advised for wave and marine work? (7) What colours (carbon) do you recommend as best for landscape, sea, figures, fruit, and architecture? (8) Do you recommend the use of red and sea green for fruit and seascapes? Are these of an artistic?" In reply: (1) "The Art of Retouching and Finishing Photographs," by Robert Johnson. (2) "Enlarging and their Finishing," by G. Rodwell Smith. (3) There is no work specially devoted to this subject. It is dealt with in manuals. (4) "The Optics of Photography and Photographic Lenses," by J. Traill Taylor. (5) Dissolve so many parts, according to the per centage required, in water, and make the up to a hundred. (6) Any ordinary camera, whether on a stand. (7) and (8) Quite a matter of taste, and tastes greatly nowadays. Possibly the best effects will be obtained by not endeavouring to imitate the colour of the original.

The Council of the International Society of Sculptors, Painters and Gravers propose to hold a memorial exhibition of the works of their late president, Mr. James McNeill Whistler, in the National Gallery, Regent Street, London, during February and March. A great number of prominent collectors both at home and abroad have already promised their support by contributing the works they possess, and it is hoped that the public will have an opportunity of seeing a most representative exhibition of his works.

EX CATHEDRA.

One is pleased to see that the police authorities are still giving their attention to the traffic in a certain class of picture postcards. On Friday last a man with a foreign name, residing in Wardour Street, appeared to answer two summonses at the Marlborough Police Court for exposing objectionable pictorial postcards. Mr. Muskett, who prosecuted for the Commissioner of Police, asked the magistrate to take a serious view of the case, and we are pleased to say he did so, for he mulcted the defendant in the substantial sum between thirteen and fourteen pounds in fines and costs. This will discount the profits he has made on the sale of these disreputable things, which it was said were produced abroad, where nearly all these indecent things come from. It is a pity the police authorities do not take steps to stop the importation of this class of postcards, for it is illegal to export pictures of an indecent character, and they may be stopped at the Customs House. The picture postcard has now become such an important and lucrative industry in this country that its popularity should not be marred by these indecent productions. Coarse and vulgar pictures did such years ago to kill the popularity of the stereoscope, and would be regrettable if they did the same with picture postcards. Stationers and others would do well to consider this matter, for we have seen in well-to-do shop windows cards which, though they could not be classed as indecent, were of a highly coarse and vulgar nature, and such as would give offence to a refined mind. There is no harm in a comic picture; it is amusing. But when it borders on the vulgar or indecent it is quite a different matter.

The Future of Photography for Employees.

The Editor of "Wilson's Photographic Magazine," commenting on an article in a recent issue of the BRITISH JOURNAL OF PHOTOGRAPHY dealing with this topic, compared the methods that obtain in England with those in the United States. He remarks:—"It may readily be understood that the situation offers some very puzzling problems to our English cousins, and we believe that the system of apprenticeship is responsible for the growth of it. We have troubles of our own in this country, no doubt, but this is one that is foreign to us. The same tendency to substitute female help for male help, which is complained of there, prevails with us, but we believe without the disastrous consequences that seem imminent on the other side. While the market may be overstocked with applications for situations, the man or woman employed possessed of the right kind of information need not despair as to the future. If his or her education is of the right kind the opportunity may be found in which to apply it in almost any of the larger cities or towns. It is true there are many who find it almost impossible to obtain permanent positions. Does it ever occur to these unfortunates that the fault is not all on one side? There are operators and operators, reception-room assistants and reception-room assistants, but among them all there are those who tower pre-eminently above their fellows. If by chance they desire a change of employment, opportunities flock to them. It is thus in every business or profession, and the man or woman possessed of the greatest amount of practical information in his or her sphere, and also capable of applying it with the least friction may be sure of success. Absence of friction in this case means adaptability to conditions and circumstances. In the case of a reception-room assistant, for instance, she who possesses the knowledge of human nature, in addition to the technique of her profession, is seldom out of employment." The situation seems to sum itself up in the short phrase, "personal equation," and if this is so, it should hold forth a gleam of hope and encouragement, even to the most unfortunate plodder.

Self-toning Paper.

The heat wave from which we have all been more or less suffering since "the dog days" commenced, must have given quite a spurt to the use of self-toning paper, for this excellent material has a collodion surface, upon which lukewarm water and hot fingers make no impression whatever. Indeed, as most of our readers know, it can be dried before a hot fire, or, dust permitting, in a hot sun. There are also some other advantages attached to this description of paper irrespective of its salamander-like qualities. The warm, brown tone of the prints lends itself admirably to

purposes of reproduction, and the block-maker is quite as content to deal with it as he is with a P.O.P. print. Then there is the question of touching up, which is an important one, especially in blocks required for the illustrated newspapers, where sometimes an obtrusive figure has to be painted out, or another put in by an artist. For the surface can easily be worked upon by ordinary water-colour tempered with a little ox gall. There is no gelatine to absorb the water, and washes, say, of Vandyke brown, can be used to strengthen shadows in a way which would be very difficult in dealing with either a gelatine of an albumen coated paper. And the surface of the paper is so hard that if touched by the finger nail in the washing water there is no tearing of the film, and no abrasion caused by the corner of another print coming in accidental contact with it. Then again, when the print is to be mounted, it can be surface-dried between sheets of blotting-paper and coated with the mountant without delay. If necessary, it can be rubbed down with a wet handkerchief without any risk of injury. The saving of time in dispensing with the tiresome toning operation, with all its risks, more than compensates for extra cost, while the saving of gold makes this method of printing a photograph a cheaper one than any other. With regard to permanence, we well know that a collodion negative is everlasting, provided that reasonable care is taken of it, and there is no reason to suppose that a collodion film on paper is less so.

* * *

The Chantrey Bequest.

A few weeks back we referred to the question that had been raised in the House of Lords with reference to the administration of the Chantrey Bequest and the discussion upon it, which resulted in a Select Committee being appointed to inquire into the matter. That Committee has now held several sittings, and numerous witnesses have been examined. The principal question seems to be what was the original intention of the generous bequeather when he made his bequest. Was the money to be spent on the purchase of meritorious pictures by what, at the time being, are unknown artists, as an encouragement to them and of British art? Or, on the other hand, from those who had made some mark in the British art world? There is no question that most of the works that have been purchased have been exhibited at the Royal Academy, while it is alleged works of equal merit, shown at other exhibitions, have been overlooked. Amongst the witnesses already examined are the secretary to the Royal Academy, its president (Sir E. J. Poynter), Sir William Richmond, R.A., Sir J. Alma-Tadema, R.A., Mr. Marcus Stone, R.A., Brock, R.A., Val Prinsep, R.A., Seymour Lucas, R.A., and many other Royal Academicians. They seem to be pretty well of opinion that the bequest has been fairly well administered. Art critics have also been examined as witnesses, one of whom said that he considered that the successive councils had been either ignorant of the terms of the will or had read the document very carelessly. He thought that the purchasers had been too much influenced by the feeling of the moment. There are other witnesses to be examined whose views, we believe, are not altogether in accord with the ideas of the R.A.s, and the report of the Committee when it is issued will be exceedingly interesting in art circles and to the public generally. The expenditure of between two and three thousand pounds a year—the sum left by the generous donor—in the furtherance of British art is no light matter for the consideration of the Committee so as to ensure that the sum is laid out to the best advantage, and also in accordance with the views of the late Francis Chantrey.

July Light.

The weather we have had during the past few weeks has certainly been a clerk of the weather. By now, as well as to the "clerk of the weather," it may be well to point out to some who, as novices, may be aware of the fact that at this season of the year the light is at times very deceptive. It may be exceedingly bright and yet be, photographically, comparatively weak, and many plates which are supposed to have received a full exposure turn out on development to be under-exposed. When the sky is cloudless, and the sun bright, the light by no means so actinic as many imagine. The strength of the sunlight is, the stronger, of course, the stronger the shadows cast, and if there are no clouds that will diffuse the light they will appear heavy in the picture through being under-exposed, and this is often the case when the picture is taken when there is a clear, dark blue sky devoid of clouds, although the exposure given was supposed to be ample. In these circumstances, the old maxim of the wet day should be observed. "Expose for the shadows, and the lights take care of themselves." One or two days last week when the light was very brilliant there was a dark blue sky, and then the actinism was at a very low level as many who had printing to do, and it was done in the shade, are fully aware. The printing took much longer than it would have done on a comparatively dull day. Those who were making daylight enlargements, with light reflected from a mirror, also found the same state of things obtaining. The dark blue sky reflected by the mirror had but a very feeble action, but here this could be at once seen by the lack of brightness in the image appearing on the focussing screen. When the sky is in the condition indicated, the mirror should be discarded and a sheet of white cardboard substituted. There is another trouble that is often encountered in hot weather, namely "heat daze"—that bright shimmering one often sees in the atmosphere, especially near the ground, on a hot sunny day when the sun is very hot and bright. If a photograph be taken through this the object will be considerably dimmed in brilliancy and lacking in sharpness. Many of our older readers will remember a picture that was shown some years ago, and at the Society's Exhibition, and which was awarded a medal. It was entitled "A Morning on the Wear." This picture, we have reason to know, was taken about midday, on a clear, hot sunny day, when there was no trace of mist. But there was plenty of this "so-called" heat haze, which is practically invisible. Indeed, we were told the negative was at first thrown aside as worthless, but was afterwards printed and given the above title.

* * *

The

Daguerreotype. There are many interesting passages in the article recently contributed to "Century Magazine" by the veteran American photographer, Mr. Bogardus. He entitles his paper "The Art of Daguerreotype," which is somewhat of a misnomer, seeing that the *modus operandi* of Daguerre is well understood, and that there is no obstacle to anyone producing such pictures. But, as we all know, there could be no demand for daguerreotypes when there are so many more convenient and better ways of making the sun do the bidding. We learn, however, from the article that there is a distinct demand for old daguerreotypes, and that there are collectors of them just as there are those who make a hobby of hoarding all kinds of things, from postage stamps to tobacco pipes. It is interesting to have placed on record the circumstance that Professor Morse, the well-known originator of the Morse alphabet, and the inventor of the first reliable telegraphic instruments, was the means of introducing the process of Daguerre to America. He visited Paris

at the time that everyone was discussing the new method of picture-making, and when the French Government was considering the question of granting pensions to Daguerre and Niepce on the condition that the process was made public property. He met Daguerre, and the latter promised to forward all particulars to America directly the pension was granted. This promise was fulfilled, and in the year 1839 Morse received the instructions and constructed the first apparatus for taking daguerreotypes which was made in the States. It may be remembered that Morse himself was subsequently gulled by the arch-imposter who, under the name of Hilltype, introduced a process for producing daguerreotypes in the colours of nature, which was simply a fraud, the pictures being skilfully coloured by hand. Mr. Bogardus has some funny stories to tell of those early days of "sun pictures." Of course, the exposures were abnormally long, and people who came to have their portraits taken had a belief, which nothing would shake, that under no circumstances must they wink their eyes while sitting for an interminable time before the lens. One old lady in the middle of the operation jumped from her chair in horror, and exclaimed, "Stop it, stop it; I winked." Another matter, one of studio etiquette, which might with advantage be revived in the cases of certain sitters, we will transcribe in the words of the writer of the article: "We always had sticky wax by us to keep wing-shaped ears from standing out from the head." And again: "We often placed a wad of cotton in hollow cheeks to fill them out." From these extracts it will be seen that the spirit of the retoucher was abroad long before it became possible to use a lead pencil on a photographic surface. But perhaps the most interesting feature of the article is its illustrations, which are taken from old daguerreotypes and reproduced in half-tone blocks of that high quality for which the "Century" is justly renowned. It is a combination of the old and the new in photography which all will appreciate, and block makers in this country will look with the eye of envy upon the name of the "engraver" attached to each of the illustrations. We cannot help thinking that if it were the custom over here to honour the block maker by such honourable mention it would tend to the production of better-class work all round.

DARK-ROOM TROUBLES IN HOT WEATHER.

THAT there should be a recrudescence of the difficulties surrounding the dark-room worker during the recent spell of almost tropical heat, seems as natural as the call for the perennial advisory suggestions for the alleviation thereof on our part. The weather we have been subjected to of late must surely have formed the subject of more than one diligent photographer's comments whilst in the depths of his dark-room, and while it is doubtful whether anything really new can be offered in mitigation of the discomforts experienced during an enforced occupation of a stuffy, dimly-lit room, with the temperature at eighty degrees odd outside, the fact remains that certain undesirable manipulatory conditions arise coincident with the arrival of the hot weather, which, unless taken in hand and dealt with intelligently, remain until its departure.

We are all unfortunately familiar with the frilling trouble. This particular fault, however, we are pleased to note, is rapidly becoming a thing of the past, and unless the worker is particularly careless, is not likely to occur often. There are many causes for "frilling," some of which are under the control of the photographer. For instance, it is often caused by using a developer too strong an alkali, or by not keeping the various solutions used, at an equable temperature. Whether the plate-makers have now discovered the exact formula from which an emulsion can

be made that remains (in the form of film) firmly attached to its glass support at a temperature above the normal 60 deg. recommended for developing, we cannot say, but it is nevertheless true that fewer cases of negatives frilling during development occur every year. A slight frilling at times, however, seems inevitable when the weather is very warm. When it appears, the developer should be carefully poured off at once, and the plate washed in several changes of water. It should then be immersed in a bath composed of $\frac{1}{2}$ oz. of chrome alum to 20 oz. of water, for three or four minutes, when it is again well rinsed and the developer re-applied. Amidol will be found an excellent hot-weather developer because of its not requiring the assistance of an alkali to become operative.

A good formula is as follows: To 50 oz. of water add 2 oz. of the best recrystallised sulphite of soda and 20 grains each of bromide of potassium and citric acid. When ready to develop add $2\frac{1}{2}$ grains of dry amidol to each ounce of the above. If further precautions are necessary to prevent softening of the film, place the plate in a bath composed of one part of formalin in fifty parts of water, for a few moments. Formalin added to the fixing bath will also assist. The following formula is suggested: Regular hypo solution, one in four, 1 gallon; metabisulphite of potassium, 1 oz.; formalin, 1 oz. Working in this manner and with the formula given above, the use of ice can be dispensed with in the most sultry weather. Even where no damage to the film is expected it is well to employ a little formalin in the fixing-bath or to use a bath after fixing in order that the negative may be blotted off and dried rapidly so that circular depressions sometimes resulting from slow drying in a warm, damp atmosphere may be avoided. A greater evil, however, than slight frilling at the edges of the negative arises if the wet plate is held for too long a period in the hands for examination. This consists of a general deliquation of the gelatine in the neighbourhood of the warm fingers. The film simply melts away, leaving the bare glass in unsightly patches around the edges of the negative. The remedy for this is, of course, obvious.

The less one handles plates, films, and gelatino-chloride papers during warm weather the better. The higher temperature of the water and all solutions is no doubt trying enough to the easily-soluble gelatine, and the additional heat imparted by the hands might easily overcome the gelatine's power to resist melting. When toning P.O.P. during the hot weather it is absolutely necessary that the solutions be cool to obtain the best results. To cool a bottle of solution of any sort whatever, a good plan is to wrap a wet towel around the bottle and place it in a current of air, such as on a window-ledge with the window open to create a draught, or hung up by the neck in an airy passage. The evaporation of moisture from the towel thus produces an appreciable diminution of temperature. The gelatine surface of P.O.P. when wet is also easily melted, and nothing is more unpleasant than to find, if a print has to be handled a little more than usual, that the heat of the fingers has caused it to become sticky and liable to injury. A good plan is to place the prints as they come from the printing-frame into clean water, then, after a few minutes, drain the water off and renew it, doing this a third time, and then transfer to a strong solution of alum and water; follow this with three further changes of water, and the prints will be ready for toning, and when finished will be sufficiently hard to ensure their not sticking if dried in contact with ferrotype plate or glass.

In hot weather gelatine prints often present a very yellow appearance when thrown into the fixing bath, the tone which they have acquired appearing to dissolve com-

pletely away. When the toning bath is warm, P.O.P. prints appear to tone very rapidly, but the tone is on the surface only. To make sure that the operation of toning has been carried far enough, the prints should be judged by looking through them, no notice whatever being taken of their surface appearance.

The drying of negatives is also worthy of attention during the summer. The rapidity with which they dry appears to have an influence on the grain. Those which dry slowly, as they would tend to do in hot weather, have a coarser, less pleasing grain, and the gelatine often seems to swell during the drying. The best thing is a cool room, away from the dust, in which the drying can be hastened by an electric fan, if possible. Wherever the plates are put to dry, they should be left there, since differences in the rate of drying such as might be brought about by removing the partially dried plate to another place, cause noticeable differences in the appearance of various portions, the line of demarcation often being distinctly visible. Reticulation, the plate seeming covered with a network of fine interlacing lines, is sometimes caused by changes in the temperature of the solutions. For example, it might be easily brought about if the developer were somewhat warm, the hypo, on the other hand, cold and pretty strong, while the wash-water was rather warm again. Tiny pits or sunken places sometimes appear in the film, especially if it is dried slowly.

The proper ventilation of the dark-room is an important question in hot weather. The health of the person demands a change of air if much work is to be done. This can be done easily by having the frame of a box set in at the top and bottom of the door, with partitions inside the box projecting two-thirds or so across, so that while the light is excluded, the air, not being compelled to move in straight lines, can wander in. If possible, the dark-room light should be placed outside the room, so that it shall not help to use up the usually scanty supply of oxygen, to say nothing of the disagreeable odours which dark-room lanterns emit. If nothing more is done, at least provide covers for the trays, so that it will be possible to go out and breathe for a few moments, if the operation should be prolonged. Good ventilation is absolutely necessary if the room is to be kept cool. When not in use the door of the room should be left partly open. The floors should also be sprinkled occasionally with water; this helps to keep down both the temperature and the dust.

In conclusion, avoid touching as much as possible the gelatine surface of either plates of papers while the fingers are at all warm. It is not wise to touch the sensitive surface at any time, but in hot weather the slightest touch of perspiring fingers will leave a mark that it will be impossible to eliminate.

THE bottom of the sea near the shore and in shallow inlets can be better seen from a moderate height, as from a balloon, than from the surface. It is proposed by a French engineer to make use of captive balloons to chart by observation and photography dangerous waters, making the observations more accurate than by soundings.

ACCORDING to reports from Kazan, the famous picture of the Madonna, which is kept in the Bogoroditzky Monastery, has been stolen. The theft of this miracle-working picture now is likely to make a deeper impression on the masses of Orthodox Russia than the news of a lost battle in the Far East. It was one of the things held most sacred in the country, and was invoked in the prayers of high and low—of Czars, noblemen, and peasants. Apart from its miraculous virtues, the picture was of great intrinsic value, on account of its precious frame, which was adorned with an immense quantity of jewels presented by Czars and others, and valued at many million roubles.

THE STEREOSCOPE AS A TEACHER IN ANATOMY.

It is just about forty years ago that the stereoscope arrived at the very zenith of fame and popularity. It waned and sunk to the nadir of oblivion till a few years ago, since when every effort has been made to popularise it as a special and attractive branch of photography. The little success that has attended these efforts is to be explored, but, even yet, we are not without hope of the beautiful effects of a good stereoscopic view appealing to a large number of workers. It is fairly well understood why the stereoscope fell so quickly out of favour—to a degree thorough that there is a generation of adults now living who, at any rate until quite recently, had never actually seen through a stereoscope. Out of this generation, where the beauties of binocular photography are made familiar to them, may we not hope that a new band of stereoscopic workers will arise? The artistic aspects of photography have been so much brought to the front for a long time past that the special and peculiar beauties of the two pictures that required to be viewed through lenses have perhaps been rather looked down upon. All this may change. But there is another aspect of stereography—where, indeed, was the cause of our treating this subject at all just now—the possibilities it affords of giving instruction upon the solid aspects of certain subjects hitherto only treated by flat photographs or drawings. We refer to the representations of anatomical structure, human or comparative. The information afforded to a medical or other student by the most beautifully executed engravings is never thoroughly satisfactory, especially when less frequently seen lesions or pathological conditions are depicted. Here a properly-executed stereoscopic view of the subject would be of infinite value, and bring the student in his study face to face, as it were, with the actual object itself. It is difficult to overstate the case for the stereoscope under such conditions. We are pleased to find that the advantages of this mode of representation has been seen by others, and that it has been brought into use by publication in the ordinary manner. A stereoscopic atlas of anatomy is now being published, as we mentioned last week, and advances proofs of some of the plates have already been issued. The success or otherwise will, of course, depend upon the technical knowledge of stereoscopic and general photography possessed by those who take the photographs; if well done they will be of great value to biological as well as medical students. Of course, such illustrative binocular photographs have before appeared with regard to books of travel, and to the teaching of geography, but not always with great success. The process of the day—the half-tone block—is not well adapted, and collotypic illustrations may easily come off devoid of sharpness and pluck. We cannot but think that bromide prints, producible, as they now are, so readily, quickly, and with such delicate rendering of detail, with as much brilliancy as can be desired, are more likely than any other to give the greatest amount of satisfaction. With regard to the optical aspect, it is evident that many kinds of effects, some good, some the reverse, are within the powers of the photographer by the mere alteration of the distance apart of the lenses employed to take the views. It would be a very easy matter to give undue prominence to an unimportant detail, and throw the student astray. But this we do not doubt will be seen to, and we hail this publication as a step in the right direction, in the teaching, at any rate, of anatomy.

We have just received a handy little volume from Messrs. Daborn and Ward, Ltd., entitled "Photography on Tour." We hope to review it in our next issue.

ON THE ALTERATION OF METABISULPHITE OF POTASH AND OF BISULPHITE OF SODA WHEN EXPOSED TO THE AIR.

In our previous studies* we have demonstrated the behaviour of crystallised and anhydrous soda sulphite when exposed to the air under varying conditions. In the present research the effect of the air on metabisulphite of potash and bisulphite of soda—the two other derivatives of sulphurous acid employed in photography—has been the subject of investigation. Namias† has recently declared that metabisulphite of potash, $\text{K}_2\text{S}_2\text{O}_5$, which crystallises anhydrously, undergoes no appreciable alteration on exposure to the air in crystallised state. The slight diminution of strength in sulphurous acid which results after a fairly long period does not, according to Namias, arise from oxidation, but from loss of sulphurous acid. On the other hand, he indicates that solutions of metabisulphite alter somewhat quickly, although less rapidly than solutions of soda sulphite. Furthermore, bisulphite of soda, according to the same author, is considerably more unstable than metabisulphite of potash when exposed to the air. In the following study we have investigated the action of air on metabisulphite of potash and bisulphite of soda, both in solid form and in solution, under various conditions.

A.—ALTERATION OF METABISULPHITE OF POTASH.

1. Metabisulphite of potash in solid form. Several portions of a sample of crystallised metabisulphite of potash were exposed to the air, in thin layers, under different conditions, one portion being subjected to comparatively dry air at a temperature of 15 deg., another to a very humid atmosphere also at 15 deg., a third at 45 deg., and a fourth at 100 deg. Each portion was titrated by liquor of iodine, first at the commencement of the trials, then every third day, operating in the manner as indicated in regard to the titration of sulphites. The results obtained in each case confirm the opinion expressed by Namias, viz., that metabisulphite in solid form appears to suffer no appreciable alteration.

2. Metabisulphite of potash in solution. Our experiments were carried out on 1 per cent., 2 per cent., 6 per cent., 10 per cent., and 20 per cent. solutions, contained in half-full two-litre bottles. For each degree of dilution we utilised a closed and an unclosed bottle. The solutions are titrated at the outset, then every third day, in the same manner as soda sulphite solutions. The following table indicates the quantity of oxidised metabisulphite in the various solutions, three and six weeks respectively after their preparation:—

Nature and strength of Met. Pot. Solution.	Duration of contact with the air.	Quantity of oxidised product per 100 gr. of total used.		Quantity of oxidised product in 100 c.c. of solution in open bottle after 6 weeks.
		Open bottle.	Closed bottle.	
1 per cent. solution.	After 3 weeks	22 p.c.	11·66 p.c.	0 gr. 56.
	After 6 weeks	56·66 p.c.	28 p.c.	
2 per cent. solution.	After 3 weeks	19·66 p.c.	8·5 p.c.	0 gr. 98.
	After 6 weeks	49 p.c.	20 p.c.	
6 per cent. solution.	After 3 weeks	19 p.c.	3·5 p.c.	2 gr. 70.
	After 6 weeks	45 p.c.	11 p.c.	
10 per cent. solution.	After 3 weeks	16·66 p.c.	2·86 p.c.	4 gr. 16.
	After 6 weeks	41·66 p.c.	4 p.c.	
20 per cent. solution.	After 3 weeks	12·66 p.c.	0·3 p.c.	6 gr. 5 p.c.
	After 6 weeks	32·66 p.c.	1 p.c.	

Notable differences are observable on comparing these results with those given by solutions of anhydrous soda sulphite of similar strength.† Thus the 1 per cent. of anhydrous soda sulphite, in an open bottle, under the same conditions as the 1 per cent. solution

of metabisulphite is totally oxidised after one week, whilst after a period three times longer only about 22 per cent. of the quantity of metabisulphite used is oxidised. In the case of the 10 per cent. solution, whilst less marked than that at 1 per cent., the difference is nevertheless strongly in favour of metabisulphite. After one month about 98 per cent. of sulphite is oxidised as against 41·66 per cent. of metabisulphite at the end of six weeks. With a 20 per cent. solution sulphite oxidises less rapidly than metabisulphite. In fact, after one month there is only 14 per cent. of oxidised sulphite as compared with about 19 per cent. of metabisulphite at the end of the same period, and 32·66 per cent. after six weeks. Therefore, it will be seen that as regards oxidation in the air, the effect of concentration is considerably less important on solutions of metabisulphite than in the case of sulphite of soda.

B.—ALTERATION OF BISULPHITE OF SODA.

1. Crystallised bisulphite of soda.

We prepared crystallised bisulphite of soda by concentrating, by evaporation, the commercial solution of bisulphite of soda as far as the commencement of crystallisation, and cooling rapidly. After drying on a plaster slab, the crystals were pressed between double filter-paper, their yield in sulphurous acid being then determined. In order to avoid a product too greatly liable to alteration, we did not use commercial crystallised bisulphite of soda in these experiments.

The bisulphite was divided into two portions and exposed in a thin layer to ordinary temperature of 15 deg., one in comparatively dry air, the second in very humid air. These products were subjected every third day to titration with a solution of iodine at one-half décime normal, operating on 100 c.c. of solution at 10 gr. per litre.

The results of these titrations, expressed in c.c.[‡] of liquor of iodine one-half décime normal, are given below:—

Duration of contact with the air.	Exposed in comparatively dry air. 15 deg.	Exposed in very humid air. 15 deg.
Initial titration	19 cc. 1	18 cc. 1.
After 3 days	24	16·2
After 9 days	37·2	15·3
After 7 weeks	16·2	14·7

It will be seen that crystallised bisulphite of soda at first becomes richer in sulphurous acid. This is probably due to loss of water from crystallisation, for the increase corresponds with an efflorescence of the crystals which becomes more and more accentuated. The product then loses sulphurous acid, its sulphurous odour disappears, and it probably becomes transformed into anhydrous sulphite according to the equation—

Further, the alteration in very moist atmosphere will be seen to be considerably more rapid than in dry air.

2. Bisulphite of soda in solution.

We have experimented on solutions containing, respectively, in 100 c.c., 1 gr., 2 gr., 6 gr., 10 gr., 20 gr., 40 gr., 100 gr., of a commercial solution of soda bisulphite as well as on the commercial solution itself undiluted, using in each case one litre of solution contained in a two-litre bottle, and using for each dilution a closed and an unclosed bottle. Daily titrations as carried out in the experiments with metabisulphite of potash gave results entirely comparable to those obtained with that compound.

The solutions of bisulphite appeared nevertheless a little more oxidable than those of metabisulphite of potash. Thus the quantity of bisulphite oxidised after three weeks, using an open bottle, is 37 gr. per 100 gr. of commercial bisulphite used in the solution containing 1 gr. of commercial bisulphite of soda in 100 c.c.

* Bulletin de la Société Française de Photographie," 1903.
† Bulletin de la Société Suisse de Photographie," 1903, pp. 516 and 518.
‡ In comparing these results Anhydrous Sulphite is preferable to crystallised sulphite, as Metabisulphite of potash, although crystallised, is an anhydrous salt.

In the case of metabisulphite these same numbers were:—

With the 2 p.c. solution the quantity of oxidised sulphite is about ...	34 gr. 0
" 6 p.c. "	32 gr. 0
" 10 p.c. "	29 gr. 0
" 20 p.c. "	23 gr. 0
" 40 p.c. "	13 gr. 0
" 100 p.c. "	5 gr. 0
With the commercial solution "	1 gr. 5
23 gr. p.c. of Metabisulphite in the 1 p.c. solution.	
19 gr. 66 p.c. "	2 p.c. "
19 gr. p.c. "	6 p.c. "
19 gr. 66 p.c. "	10 p.c. "
12 gr. 66 p.c. "	20 p.c. "

The numbers obtained with the bisulphite of soda are markedly higher than those obtained with metabisulphite of potash, but we notice that the commercial solution of bisulphite of soda contains in reality only 40 per cent of NaHSO_3 . If the solutions be brought to comparable strengths in sulphite composition we find numbers comparable between them, but nevertheless lower for metabisulphite of potash than for bisulphite of soda.

CONCLUSIONS.

The preceding experiments enable us to draw the following conclusions:—

- (1) Crystallised metabisulphite of potash does not appreciably alter either in dry or moist air.
- (2) Solutions of metabisulphite of potash kept in contact with the air alter. This alteration is markedly less than that of corresponding solutions of soda sulphite in the case of diluted solutions. On the contrary, the alteration is greater in the case of metabisulphite of potash than in that of soda sulphite when the concentration reaches 20 per cent.
- (3) The influence of the concentration of solutions on their oxidability in the air is much less important with metabisulphite of potash and bisulphite of soda than with sulphite of soda.
- (4) Crystallised bisulphite of soda is very liable to alteration in the air, but solutions behave almost in the same manner as those of metabisulphite of potash.

From a practical point of view the result of our experiments on the alteration of different derivatives of sulphurous acid used in photography when exposed to the air is that for the preparation of developers anhydrous sulphite of soda appears to be preferable to the other derivatives of sulphurous acid.

Diluted aqueous solutions of metabisulphite of potash, although slightly less alterable in the air than those of anhydrous soda sulphite, present the grave inconvenience of necessitating the addition of an exactly calculated extra quantity of alkali at the moment of development, which, from our point of view, would cause metabisulphite of potash to be rejected as an alternative to the use of anhydrous sulphite of soda in practical work.

A. AND L. LUMIERE AND A. SEYEWETZ.

SPOILING Hampstead Heath.—One of the most charming views in the northern suburbs is in immediate danger of being ruined by the cheap builder, and the Hampstead Heath Extension Council, in the name of all Londoners, is engaged in a praiseworthy effort to save it from this fate. Looking out north-west from the slopes beyond Spaniards Road the eye is carried down a lovely vista of undulating ground, green glades of grass alternating with thickets of hawthorn and bramble, to where the country opens out to a typical stretch of English meadow land, an expanse of pasture and hedgerow elms extending away uninterruptedly to the hills on the sky line. This pleasant green middle distance of sward and pastoral hillock is absolutely essential to a picture which has delighted generations, and ought by every possible argument to be left unharmed. Yet it is right across this priceless little reminder at our doors of how beautiful the real country is that the builder will march ruthlessly unless something is speedily done to save a view, unmatched of its kind perhaps in the neighbourhood of the great city, from complete destruction.

THE CONVENTION.

THE Photographic Convention of the United Kingdom of its nineteenth annual meeting in Derby on Monday, July 19, was in glorious weather. Various places and objects of interest in the town were visited during the day, and in the evening delegates were officially welcomed by the Mayor (Council C. Boam) in the Albert Hall. The guests, who numbered about 400, were received by his worship between 7.30 and eight o'clock, and the President (Mr. G. Herbert Strutt) afterwards delivered his inaugural address. Mr. C. H. Bothamley (a past president) occupied the chair at the outset, those also on the platform being the President, the Mayor, Mr. John Stuart, and William Crooke (past presidents), the hon. secretary, treasurer (Mr. F. A. Bridge), Mr. Alex. M. Rodger (Past President) and Mr. W. Crowther (local hon. secretary).—The Mayor tendered a hearty welcome to all present, and expressed pleasure to notice that the first annual gathering of the Convention was held in Derby in 1886. They had, he said, their county some of the best scenery in the kingdom, and hoped their second visit would prove in every way an enjoyable one.

The Chairman expressed regret at the absence of Sir Robert Pullar, the retiring President, with whom, he said, they sympathised in the great loss he had sustained. He warmly thanked the Mayor for the hearty welcome he had extended to them, he remarked that since their meeting in 1886 the Convention had grown, and had become a more prosperous body. To anyone in Derby or the county was absolutely an unnecessary proceeding to introduce a new President, for the family of Strutt was well known so intimately connected with all that was active in their public life. He then asked Mr. Strutt to take the chair, and Mr. Rodger, acting as Sir Robert Pullar's deputy, handed to him the badge of office.

The President, who was very heartily received, said his object was to thank them for the great honour they had conferred upon him by electing him President for the coming year. When he looked at the catalogue of names of presidents who had preceded him, names well known in the scientific world, he felt he could hardly expect to follow in their footsteps as well as he should like, and he could hardly hope to come up to their expectations. But he was well aware how it was he came to be elected to that office. Everybody in the Photographic Society of Derby, and everybody in Derbyshire, thought, as well as all the members of the Convention, would have liked to have elected Sir William Abney, who happened to be his cousin, to that position. But Sir William Abney knew he would be away on the Continent at that time, and a kind friend of his mentioned himself as a possible substitute. Whether his name was put forward simply because he was the relative of Sir William Abney, or because he happened to be President of the Derby Photographic Society for the year, whether it was put merely as that of a local man taking interest in local affairs, he did not know, but he knew they were good enough to take him upon trust, and he responded to their invitation and accepted with very great pride the honour they had conferred upon him for the coming year. He claimed that he had upon the consideration of the photographic world was that for twenty years he had been a painstaking amateur, and he had derived so much pleasure from the pursuit of photography, and it had proved of such immense value to him, even with his very limited knowledge of it, that whenever he got the opportunity he tried to interest others in the art. He did not forget, as the Mayor had reminded them that that Convention had visited Derby before. He still remembered their coming in 1886, and he was very glad they had come again, although he feared at the present time the streets of the town were not in a very attractive condition for photography. However, no great improvements in D

could be carried out without a good deal of dislocation of the traffic and inconveniences of other kinds, and although it was unfortunate that it should have happened at a time when an important Convention was visiting the town, still, he hoped they would understand it. But they were not going to spend the whole of the week in Derby; they were going to visit scenes of which they were justly proud — Dovedale, Haddon Hall, Hardwick, and other places, and which would doubtless be photographed, and he ventured to prophecy that when the week was over and they had returned to their homes they would carry with them some pleasant memories, and he hoped some excellent negatives, of the places they had visited. For his own part, he was certain of this, that all who had had a voice in organising the arrangements—in fact, everybody in the town and county of Derby who took any interest in photography, and the public in general in Derbyshire would do their very best to give him a hearty welcome, and to make their stay in the county a pleasant one. And he thought that it was only right that this should be so, because photography had done an immense amount for the public. They could look back on the old days when photography was in its infancy, and they could see to what an extent it had grown. Why, when they first visited Derby he believed their numbers were only 46, while last year they numbered 340. There at once was an enormous increase, and they had only to look round their own neighbourhoods and note the number of photographers they could count to see how enormously the art of photography had increased. The specimens they saw around the walls represented the highest art in photography, and when they came to look back upon the old photographs of thirty or forty years ago, how very poor they seemed compared with their present works. Yet they must not forget that the pioneers of those days deserved their gratitude. They were working with instruments and processes which were very much harder to manipulate, and it was very interesting to be able to look back on their work, and to see that they produced work as good as it was. Again, if they turned to the apparatus of to-day what changes there had been. The hand camera had come into vogue in a most surprising manner, and he thought they owed a debt of gratitude to those firms who had turned their attention to its perfecting. Inventions came so rapidly that when they thought of telegraphy without wires they might possibly come to photography in colours before any very great length of time. However, after his twenty years of experience, the only definite conclusion he had arrived at was that he knew very little about the art at all, and he thought most of them were standing on the verge of knowledge, and that they had a great deal to learn. The object of a large Convention like that was to bring together those who were deeply interested in the art, and by the interchange of thought, and by the reading of scientific papers to see whether some future possibilities might not be discovered in the art of photography. The Convention had done a great deal in the past, and he felt confident that the visit to Derby would be productive of good fruits. He only hoped that everything would go off well, and he could only add that he was particularly glad he would be able to show them a little hospitality on Wednesday.

On the motion of Mr. John Stuart, seconded by Mr. William Crooke, the President was warmly thanked for his address, and subsequently the company inspected the collection of photographic apparatus, pictures, etc., on view, and enjoyed an excellent selection of music by an orchestral band, under Mr. H. J. Bouldersstone, vocal music being contributed by Miss Bernice Woods, Miss Hollingworth Innes, and Mr. Herbert W. Gambridge. Light refreshments were served during the evening, which was altogether a most enjoyable one.

On Tuesday the whole day was spent at Dovedale, the leader being Mr. T. A. Scotton (Derby). The party proceeded by brake to Ashbourn, which was reached about half-past ten. An hour's

ramble followed, and, the day being fine, some excellent negatives were secured. The party next resumed their journey to Dovedale, where luncheon was provided at the Peveril Hotel. The members in the afternoon separated into small parties, and visited the various places of interest, taking the opportunity to obtain some permanent records of their excursion in the form of landscape views. At five o'clock the party re-assembled, and drove to Ashbourn, where tea was provided.

THE ANNUAL MEETING.

The annual business meeting of the Convention was held on Wednesday morning at the Mechanics' Institute, Derby. In the absence of Mr. G. Herbert Strutt, J.P. (President), Mr. C. H. Bothamley was voted to the chair, and there was a very good attendance.

After the minutes of the last annual meeting had been confirmed, the meeting discussed the place of meeting for next year's Convention.

A letter was read from the Photographic Society of Ireland, asking the Convention to meet in Dublin.

On the proposition of Mr. Lyell (London), seconded by Mr. G. W. Norton (Oxford), it was decided to accept the invitation. The following gentlemen were elected on the Council: — H. Walter Barnett (London), Harold Baker (Birmingham), Godfrey Bingley (Leeds), Henry Coates (Perth), W. J. Croall (Edinburgh), T. R. Dallmeyer (London), W. E. Dunmore (London), Alfred Ellis (London), S. H. Fry (London), F. Gandy (Derby), T. K. Grant (London), Dr. E. Collier Green (Derby), H. M. Hastings (London), E. J. Humphrey (London), Martin Jacquette (London), C. B. Keene (Derby), Sydney Keith (Hounslow), G. T. Lee (Derby), C. Phipps Lucas (London), J. W. Marchant (London), A. F. Mowl (Liverpool), John Noaks (Croydon), G. W. Norton (Oxford), Rev. T. Perkins (Blandford), Arthur Priestley (Birkenhead), Ralph Robinson (Redhill), J. A. C. Ruthven (Dublin), P. R. Salmon (London), F. H. Sanderson (Cambridge), T. Scotton (Derby), A. Seaman (Chesterfield), Alexander Tate (Belfast), W. Taylor (Leicester), J. H. Walker (Leeds), E. J. Wall (London), H. Snowden Ward (London), Major-General J. Waterhouse, I.S.C. (London), S. B. Webber (London), J. B. B. Wellington (Elstree), and A. Werner (Dublin).

Mr. H. Snowden Ward proposed a hearty vote of thanks to their hosts at Derby (the Mayor and the Town Council). He said they had never been better received than they had been at Derby.

Mr. W. Crooke seconded the motion, which was unanimously agreed to.

The auditors were re-elected, and the Chairman said that they did not often get members at the meetings from the British dominions beyond the seas, but this year they had three members from Cape Town attending the Convention.

Mr. Furniss proposed that the balance-sheet of the Society be circulated amongst all the members of the Society, and this was agreed to.

The Hon. Secretary (Mr. F. A. Bridges) said that the Society had about £450 in hand, and of that amount £300 had been collected since he had held the office of secretary.

The meeting concluded with a vote of thanks to the Chairman for presiding.

THE GARDEN PARTY.

On Wednesday afternoon the President and Mrs. Strutt gave a garden party at their charming residence, Bridgehill, Belper. Besides the members and their lady friends, invitations had been extended to a number of well-known local amateur photographers, and considerably over 200 ladies and gentlemen assembled at the Midland Station, Derby, on Wednesday afternoon, and proceeded by the 2.15 train to Belper, where they were joined by several others who had motored over. The weather was gloriously fine, and the splendid grounds at Bridgehill were seen perhaps at their best. Upon arrival at

Bridgehill Mr. and Mrs. Strutt held a reception in the house, and extended a most cordial invitation to all present. The company spent an exceedingly delightful afternoon in wandering about the grounds, listening to the fine band of the 1st V.B. Sherwood Foresters, under the conductorship of Bandmaster Seddon, and partaking of Mr. Strutt's generous hospitality. The band was situated on the upper lawn, and the following is a programme of the pieces played:—Overture, "A Merry Monarch" (Herold); waltz, "Wiener Kinder" (Strauss); selection, "The Toreador" (Monckton); cornet solo, "Shepherd of the Fold" (Piccolomini); fantasia, "A Life on the Ocean" (Miller); piccolo solo, "Lilliputian" (Brewer); selection, "Faust" (Gounod); waltz, "Fesche Geister" (Strauss); selection, "The Red Hussar" (Solomon); negro dance, "Sambo's Holiday" (Tchakoff); selection, "My Lady Molly" (Monckton); fantasia, "Irish Melodies" (Hare); "God save the King." During the course of the afternoon the whole of the members of the Convention assembled on the upper lawn, and the "official" photograph was taken by Mr. C. Barrow Keene, a reproduction of which is presented with this issue of THE BRITISH JOURNAL OF PHOTOGRAPHY. A key to the group will be published in our next issue. Tea was provided in a large tent on the lower lawn, whilst on the upper lawn there was a large tent for fruit and other refreshments. The catering was satisfactorily carried out by Mrs. Stone, of the County Hotel, Derby. Mr. and Mrs. Strutt did all in their power to make the gathering a delightful one, and they were eminently successful in their efforts. The party left Bridgehill shortly after five o'clock, and travelled to Derby by the 5.30 express, which was specially stopped for them at Belper.

THE ANNUAL DINNER.

The annual dinner of the members of the Convention was held at the Royal Hotel, Derby, on Wednesday evening, and proved very successful, the gathering being graced by a number of ladies. Mr. G. Herbert Strutt, J.P., presided, and he was supported by the chief officers of the Convention. Amongst the local gentlemen present were the Mayor (Councillor C. Boam), Councillor Dr. Laurie, J.P., Councillor H. Arnold Bemrose, J.P., Dr. E. Collier Green, Messrs. C. B. Keene, F. Cooper, G. Walker, H. G. W. Dawson, W. Crowther, W. R. Bland, and others. An excellent repast was provided, and at its conclusion an interesting toast list was submitted. The loyal toasts having been duly honoured, Mr. H. Snowden Ward proposed the toast of the evening, "The Photographic Convention of the United Kingdom." He said that the Convention was progressing extremely well, and in a manner which must be satisfactory to them all. Some critic of the Convention went so far as to assert when the Convention visited Glasgow the second time that it was a great mistake. However, the members of the Convention were so satisfied and gratified with their second visit to Derby that they had decided to visit Dublin for a second time next year. In Derby they had not only been treated extremely well by the Mayor and Corporation, but by the people as a whole.

Mr. F. A. Bridge, the hon. general secretary, in responding, mentioned that the Convention possessed a balance of cash in hand of £450. There had not been quite such a large gathering at the present conference as last year, but everything had been decidedly satisfactory and enjoyable. The members never had a better welcome, and great trouble had been taken to make the gathering a success. He could not forget that Derby was the first place at which the Convention met, nineteen years ago, and the good fellowship which existed in Derby in 1886 had continued up to the present time.

Mr. John Stuart (Glasgow) gave the toast of "The Mayor, Magistrates, and Corporation of Derby." In doing so he said it was not only the magistrates and the Mayor who had given

them such a hearty welcome and treated them so well, the whole town. Everyone had done his best to make it happy and comfortable. They owed Derby, its Mayor, and Corporation a deep debt of gratitude, and he assured them the members were quite satisfied.

His Worship the Mayor expressed his delight, and thanked his brother magistrates and the Corporation, to receive a second visit from the Photographic Convention, and he trusted it would not be long before they came again. He was very glad the members had been favoured with such fine weather, and hoped the remaining time of the visit would be spent under equally favourable conditions. His Worship paid a tribute to the beneficial results derived from the Convention, and to the good fellowship which it kindled. He wished it every success.

Dr. Laurie also responded to the toast, and endorsed the words of welcome delivered by his Worship the Mayor. He was very glad the Convention had grown to the extent it had, and he wished it every success and continued prosperity. Many people had a habit of crying down their own cities or towns, but he had never seen that Derby was worse than other towns, in fact, he considered it better than some of the towns. It was one of the healthiest large towns in England. He was very glad to say that the housing problem in Derby was not in any way acute, for the amount of overcrowding was almost reduced to an invisible unit. He joined with the Mayor in hoping that the town would soon have the pleasure of another visit from the Convention, to which he wished every success.

"The Derby Photographic Society" was the toast submitted by Mr. E. J. Humphery (London), who said they all thanked Mr. Strutt very cordially for the very pretty and highly enjoyable garden party to which he entertained them that afternoon. Mr. Strutt was the president of the Derby Photographic Society as well as holding the office of president of the Convention. Then they possessed enthusiastic gentlemen in Mr. Collier Green and Mr. Keene, a vice-president of the society who was the worthy son of a most worthy father. He asked them to honour the toast of the Derby society with every sincerity and cordiality, and he coupled with the toast the name of Mr. W. Crowther, who had been officiating as secretary for the arrangements, etc.

The Town Clerk (Mr. G. T. Lee) responded. He said the members of the Derby Photographic Society were only pleased to receive a visit from the Photographic Convention, which would no doubt urge on those who had allowed their interest to flag, and encourage those who perhaps had not done quite so well as might be.

Mr. William Crowther, who also responded, thought the Derby Photographic Society was doing everything they could to help the good cause. The Derby Society yielded to none in enthusiasm and good fellowship, and he sincerely hoped the local society would be attended with every prosperity.

Mr. George Davison submitted "The Professional Photographers' Association." He said there was one fault he had found with that association, and that was that so few of the members of that organisation were present at the annual Convention. He had hoped that they would have seen a large section of that body to share with them the enjoyments and pleasures of the Convention. However, he trusted that would be made up at another gathering, and certainly, although perhaps they lacked numbers, they did not lack quality. He coupled the name of Mr. Alfred Ellis with the toast.

Mr. Alfred Ellis, the president of the Professional Photographers' Association, in responding, said that in many of the cases the professional photographer was his own operator, it was very difficult for him to attend that Convention for a few days or a week. There was a depression in trade, which, of course, affected the business of photography more than others.

Mr. C. H. Bothamley gave "The President," and, in doing so, said that the head of their Convention was a gentleman of great importance, and he thought in every way they might congratulate themselves on the selection of the President of the Convention for the year 1904. They had a President who had taken considerable part in the preparation of that meeting, and they had all had personal experience of the kindly and generous hospitality of Mr. and Mrs. Strutt. They had found their president of the present year not only an enthusiast in the art of photography, but a thoroughly good fellow.

The toast having been drunk with musical honours, the President, in replying, assured them that when he accepted the presidency of that Convention he did so not without trepidation, but he was assured that he would get along all right as long as he helped the organising secretary and did what was required of him in that direction. He could not help feeling—and that was one of the reasons why he accepted the presidency of the Convention—that the importance of photography was not yet fully recognised. People treated it as an amusement, and as an artistic occupation, and so on, but the time had not yet arrived when people treated it as a means of making a record—a traditional record which could be valued as history. He did feel that if photography had been invented 150 or 200 years ago, records of those days would have been most valuable to the public bodies of the present day. On his own estate he never thought of having alterations made without first photographing the house or whatever it might be, and then saving the alterations photographed. He was proud to say that he had had some small influence upon the county council of the county, and if they went to the offices of that body they could see a record of the last fifteen years—a most carefully photographed record, which was the property of the ratepayers throughout the whole county. There were photographs of such things as alterations to the boundaries of the county. They were not interesting and not artistic, but they would be of great importance, and would save a vast amount of labour, to those who had to come after them. Another institution that he was deeply interested in was the Derbyshire Royal Infirmary in the town, of which they were very proud. It was an institution in which was the means of doing a vast amount of good in the town and county of Derby. Dr. Collier Green and himself met constantly there, had introduced photography, and not only did they take ordinary portraits, but, thanks to the X-rays, they "did" interiors as well. He could honestly tell them that the introduction of the X-ray into the Royal Infirmary had been very beneficial to the many who were unfortunate enough to get such things as needles into their bodies. They had found the X-rays absolutely necessary. In conclusion the president said it was an extreme pleasure to him to be able to show them any little hospitality during their stay in Derby.

The other toasts included "The Press" and "The Ladies," and the gathering concluded with the singing of "God save the King." During the evening songs were given by Mr. H. W. Hambridge, Mr. Turner, and Mr. F. A. Bridge, whilst Mr. S. Deville Cox presided at the pianoforte.

On Thursday morning the members of the Convention left Derby for Hardwick Hall, under the guidance of Dr. Green and Mr. C. B. Keene, travelling by rail to Stretton Station, and thence by coach to Hardwick. A large number of members participated in the excursion, which was a very interesting and highly enjoyable one, and many excellent negatives of the Hall and surroundings were secured. In the evening at the headquarters of the Convention, the Mechanics' Institute, a paper on "Telephotography" was given by Mr. Clifton, in the presence of Mr. T. R. Dallmeyer, F.R.A.S., who was unfortunately indisposed. The paper is given in another column. There was a good attendance, which included the chief officers of the Convention. The lecture, which was capitally illustrated

by lantern slides, was listened to with great interest, and a number of slides, prepared by members of the Derby Photographic Society, were afterwards thrown on the sheet, under the direction of Dr. Collier Green.

On Friday a visit was paid to Chatsworth and Haddon Hall under the guidance of Mr. A. H. Bennett, and in the evening, after a most enjoyable day, the meeting at the Mechanics' Institute was well patronised. Mr. H. Snowden Ward gave a paper on "Figures in Landscape," illustrated by lantern slides.

Saturday witnessed the close of the Convention, which may be marked down as one of the most successful of the series. The particularly propitious weather had no doubt much to do with the enjoyment experienced by the visitors to Derby this year, and we trust that next year's gathering at Dublin will be similarly favoured.

During the week an exhibition of photographs and photographic apparatus was held in the Albert Hall. The exhibition included unframed prints, the work of members of the Convention, and a special section was reserved for pictures taken at the Perth meeting last year. Particularly worthy of note were the exhibits by Kodak Limited and the Platinotype Company of work by the most prominent American professional photographers. Messrs. J. J. Griffin and Co. and the Adhesive Dry Mounting Company also had a display of their specialities on view. An exhibition of professional work by members of the Professional Photographers' Association was also open during the week at the Corporation Art Gallery. A brief review of this appears in another column.

In addition to the usual amount of real hard work undertaken by Mr. F. A. Bridge, the general hon. secretary of the Convention, special mention must be made of the efforts of Mr. W. Crowther (local hon. secretary) and Miss Crowther, and Messrs. J. B. Copeland (hon. secretary Derby Photographic Society), C. Barrow Keene, A. H. Bennett, T. A. Scotton, S. Finney, G. Walker, Dr. Collier Green, Bendle W. Moore, F. Willatt, and W. Wilkinson, in endeavouring to make the Derby Convention, 1904, a signal success.

THE PRESENT POSITION OF TELEPHOTOGRAPHY.*

TELEPHOTOGRAPHIC lenses have now been before the photographic world long enough for a just estimate of their practical value to have been formed, and the following remarks are intended to summarise the experience of more than a dozen years of intercourse with workers in the field of telephotography. It is unnecessary to deal with elementary principles, or to give working instructions here, for telephotography has now a literature of its own, and the beginner will find reliable guidance in the books of Mr. Ernest Marriage, the late Dr. Deller, in addition to the booklets issued by the manufacturers of the necessary instruments. Ten years ago the telephotographic lens was regarded as a scientific curiosity, which might have its uses, but that these uses were so limited, and the manipulations of the instrument so difficult, only the most ardent and skilful enthusiasts dared to invest in one; to-day it is usually due to financial considerations if the amateur's outfit does not include one, while, more wonderful still, even the professional photographer is beginning to become conscious of their existence and to realise that there is money in a lens that enables him to accomplish work which he would otherwise have to refuse as impracticable.

We can only compare the progress of telephotography with that of the phonograph, which has in like manner developed from a scientific marvel to being a source of enjoyment to the million and an instrument of real value to the scientist and

* A paper read before the P.C.U.K. by Mr. E. Clifton, F.R.P.S.

historian. I will now, with your permission, give you some reasons why people use telephotographic lenses.

The greatest and almost sufficient reason is that they allow of objects being taken from a better point of view than is usually the case, the size of the image being at the same time capable of variation between very wide limits. (This was well illustrated by the two slides shown, taken from illustrations published while the telephoto lens was a struggling youngster and showing St. Albans Abbey as photographed from a near point of view, with all the horrors of exaggerated perspective, and the same building taken at a distance of nearly a mile, of course with a telephoto lens. Here the true proportion of the Abbey towering above the surrounding buildings was seen, and the intentions of the architect are truly recorded. Almost similar was the case illustrated by Mr. Cleveland's view of Salisbury Cathedral, only here as a contrast the rendering was given by an ordinary lens at the same distance.)

Taking another case, we may find that our desired object is entirely inaccessible and that the only possibility of securing a picture is by the use of the telephotographic lens. Architectural details may be classed with the foregoing, and I am glad to say that the student of architecture has not been slow to avail himself of the new power. One of the most recent developments of telephotography is its application to the rendering of very near objects sometimes on a slightly reduced scale, and again sometimes larger than natural size. Anyone who has had experience in the photography of flowers, articles of jewellery, and the like, has felt the urgent necessity for a lens of such focal length that a comparatively distant standpoint can be chosen. The charming studies by Mr. H. T. Malby illustrate this.

From such subjects we turn naturally to portraiture, and it is gratifying to be able to record a growing tendency to use the telephoto lens in one or other of its forms in the studio. Besides the simple uncorrected telephoto lens which was made at the instance of Mr. J. S. Berghem, negative attachments of low power are frequently used for what are commonly called studies, but which it is to be hoped will become the usual thing in the near future. Work by Mr. Hewitt, Mr. Cadby, and Mr. F. H. Evans illustrate in the most striking manner the value of the telephoto lens in ordinary portraiture. A few words regarding the choice of a telephoto lens may not be amiss. Telephoto lenses may be roughly divided into two classes—high power, i.e., having a negative lens with a focal length of less than one-half that of the positive lens, and the moderate power, in which the negative focal length is one-half that of the positive, or even greater.

Broadly speaking, it may be said that the high power combinations are mostly useful for mountain scenery, architectural details, and all subjects where the maximum magnification obtainable with any given camera extension is desired. The principal drawback to their general use is that ordinary-sized plates are not covered to the corners with low magnifications.

Moderate power combinations have in every sense a wider field. They are the tool of the pictorial worker, covering, as they do, the normal-sized plates with a minimum magnification of about three diameters—(by normal-sized plates I mean the size for which the positive lens was originally chosen)—and this at practically the infinity focus of the positive lens. With most modern cameras magnifications up to $4\frac{1}{2}$ or 5 diameters may be obtained, and this degree of enlargement will be found ample for most subjects. For portraiture, the focal length of the negative lens may advantageously be longer, equalling or even exceeding that of the positive lens, and it may here be pointed out that owing to the softening effect which results from the combination of a portrait lens with a negative, the full aperture of the former may be used, so that a magnification of $2\frac{1}{2}$ to 3 diameters may be obtained with little increase of exposure

as compared with the positive lens used alone and stopped down sufficiently to get an apparently equal amount of depth of focus. In eight years the telephoto lens will attain majority as a practical working tool, and I trust—I may almost promise—that I shall then be able to chronicle further developments in its construction and use.

T. R. DALLMEYER, F.R.A.S.

SOME UNCONVENTIONAL OBSERVATIONS AT DERBY

By A BLAND OBSERVER.

MONDAY.—Reception by the Mayor and his great Gold Chain. Mr. C. H. Bothamley, in an effusive way, eulogised the President, Mr. G. Herbert Strutt, and the illustrious family from which he has sprung. Mr. Rodger, of Perth, then spoke, but he couldn't be heard, and afterwards produced what appeared to be an infernal machine. It proved, however, to be harmless, and merely contained an 18-carat gold Maltese cross which only a Convention President wears. Mr. Strutt rose gracefully, and it was stuck on him, and the honour was so enthusiastically received by the admiring and envying audience that he subsided quietly into his chair, and blushed like a maiden. There was only one smoke-room, and nearly enough chairs in it, so we sat on one another's knees on the table, the window-sills, and the floor. There were matches, and foraging parties were instituted. (Convention members can do without chairs, but they cannot do without matches.) *Per con.*, there were two refreshment-rooms—a most excellent and praiseworthy arrangement. Members lived in the hotel until the waiters knew them, then they went to the other, subsequently returning to the first one as strangers. The writer did it himself, and was poorly the next day. The only regret was that there was no whisky on draught.

TUESDAY.—Dovedale.—The writer didn't go. He knows that any one who expects to get there a pictorial picture out of a hundred photographic pictures is a—knows not what he is let in for. As a just judgment the train in the evening was three-quarters of an hour late, which gave a thunderstorm chance, and some of the members got very wet, and returned to Derby to go to bed. There was no meeting in the evening. Good job!

WEDNESDAY.—The writer was not elected a member of Council. With Japanese pluck he, undismayed, went to President's garden-party, and, following the example immediately set, found himself in the refreshment-tent, and had tea and sweet things. Shortly after he found another tent, much cooler than the first one, and claret cup and champagne cup in it. He had them. The band played, and a bugle called as per programme. The bugle called the Convention group together—see photograph, the back row, with two feet on chairs. A well-known Conventioneer pulled himself up into position by them, and, hoisting a hand-camera, essayed to snare the Convention snapper. At the critical moment he dropped the camera, and whether he reappeared with it in time to be included in the group or not the photograph will show.

WEDNESDAY.—Dinner (at the Royal Hotel).—Very well done. Waiters attentive and numerous, but no matches, not even when they were asked for. A few of the speeches were good, but short, some rather turgid and long. The President spoke well, so did Mr. Humphries and Mr. F. R. Salmon (who replied to "The Press," notwithstanding that he divided his brief speech into three heads). Mr. Humphries had a congenial subject for the toast of "The Ladies," to which Mrs. Snowden Ward responded, and was received and accompanied with plauds. Mr. F. A. Bridge and Mr. William Crooke contributed to the musical portion of the evening. The former was warmly encouraged, and the President performed departed from his room and allowed it. The second song was very pretty. Mr. Bri-

brought it out perfectly, and must have been a sad dog in his prime. Mr. W. Crowther, the local hon. sec., also gave vent to a recitation, which was vociferously applauded. The writer was again poorly the next day.

THURSDAY.—Hardwick.—Very enjoyable excursion, all but Hardwick. Photography inside the Hall was not allowed. To add to the disappointment, Mr. Seaman, of Chesterfield, discovered in some occult way that the housekeeper had orders, which she had misread, to allow the members of the Convention to photograph interiorly. The glad news was spread about at once, but, as the members were then about to pack up for the return journey it only made them wilder, and the usual urbane glee did not spontaneously illumine the remaining hours of that day. Mr. Dallmeyer was announced to read a paper on "Telephotography," and sent Mr. Clifton to do it for him. He did it, and showed a grasp and lantern-slides of his subject. The grasp was better than the slides from a pictorial point of view, the latter lacking in artistic lighting, but still good enough to illustrate the technical points of the subject. Dr. Collier Green followed with an exhibition of slides by members of the Derby Photographic Society, together with some effectively-coloured slides of flowers brought by visitors from Cape Town. (N.B.—It was slides that they brought.)

FRIDAY.—Chatsworth and Haddon Hall.—These quite wiped out the Hardwick disappointment, and the evening showed everyone to be jubilant. One member exposed fifteen plates in Haddon, and how he did it in such a crowd the writer can't imagine. Perhaps he snapshotted for the "Daily Mail" competition. There was a large audience at the Mechanics' Institute at 8.30 p.m., and Mr. Snowden Ward made an excellent speech. His subject was "Figures in Landscape." He emphasised the opinion that figures might be made a great help to landscape, and that landscape might be made a great help to figures. He showed many lantern-slides, the best of them—and two were artistically good—having been made by beginners. Some slides sent from Perth followed, several of which were of a very high degree of merit, but were spoilt by white lettering on them of the title of the subject and an index number. This meeting over, Mr. Snowden Ward, feeling more dry than usual, was conducted by a friend to the bar of the local Slater, at which he was received with cheers by Conventioners already there, and had something to drink, with ice in it, and was poorly the next day.

SATURDAY.—Going-home day, and visits to the Penny Bank on arrival for withdrawals. Some members who weren't in a hurry to go home went to Winfield Manor, a fortified domestic hall possessing cannon balls left in it by Oliver Cromwell.

FINAL.—The local members of the Convention are feeling sore. Their character has been impugned. The writer, together with the other local members, was given a Convention badge, ornamented with wings of white ribbon. This, it was explained, was that people would know him when they saw him, and if they wanted anything would ask him for it. His personal friends, however, have cut him, believing the white ribbon to mean that he has joined the Derby Vigilance and Purity Association. On his complaining of this to the local secretary, Mr. Crowther, the only reply he got was: "You may be quite sure that none of your friends who *know* you would ever think that of you."

The following formula for producing soft, warm tones on platinum papers is given in "Photographic Scraps." The amateur should, however, realise that the chemicals employed are exceedingly poisonous. Four stock solutions are to be made up, viz.: (a) Oxalate of potash 4oz., water 16oz.; (b) copper chloride 125 grains, water 8oz.; (c) mercuric chloride 1oz., water 16oz.; (d) lead acetate 32 grains, water 4oz. To twelve parts (a) add four parts (b); then add four parts (c) and one part (d). Heat to 175 deg. F. Slightly overprint the platinum paper and develop full out.

CARBON PRINTING.*

The carbon process possesses the advantages of great permanence of the prints, wide range of colours obtainable, and great latitude. Dense and thin negatives produce most satisfactory prints under certain conditions, and as the tissue can be sensitised, exposed, and developed within a few hours, the process universally commends itself, and no other process is capable of producing more exquisite pictorial results. The varieties of surface are also very great as exceedingly smooth, medium, or rough surface papers can be used according to the nature of the subject. Opal, glass, or ivory can also be used as a final support. The process depends upon the action of light upon pigmented gelatine, associated with a chromic salt. The tissue can be sensitised during manufacture or subsequently. A disadvantage of ready sensitised tissue is its inferior keeping qualities, although great improvement in this direction has been made. The ready sensitised tissue will keep for several months, however, if properly stored in boxes. The keeping qualities of tissues sensitised after coating are dependent upon the strength and condition of the sensitising bath. The first requirement is a good, pure paper which will retain its toughness when wet. It may be coated with a solution made as follows:—

Nelson's opaque gelatine	1 lb.
Coignet's gold label gelatine	4 oz.
White loaf sugar	6 oz.
Potassium bichromate	1 oz.
Water	80 oz.

Colouring matter (to suit requirements).

The potassium bichromate should be converted into double-chromate of potassium and ammonium by the addition of ammonia. The warm solution or jelly is placed in a suitable dish, and the band of paper to be coated is drawn over the surface. Another method is to draw two bands of paper together through the solution, one side of each being coated in one operation. The paper is then dried, generally upon rollers or laths.

Probably to the majority of those present the most interesting method of producing carbon prints is that known as the single transfer process, which offers many advantages over the double transfer process. By single transfer prints can be produced upon almost any surface, whereas the double transfer process limited one in that direction. In the single transfer process it is necessary first, to have a reversed negative, the graduations of which should be carefully considered. Negatives known as "plucky" require a tissue sensitised in a bath stronger than that required by a thin, delicate negative. The negative must be "safe-edged," and a good way of "safe-edging" is to paint about $\frac{1}{4}$ in. or $\frac{1}{2}$ in. round the margins of the negative on the glass side. The paint need not be opaque, and if it be slightly transparent it will answer very well. Black or brown paper pasted round the margins of the negative also answers the purpose. If potassium bichromate containing a large quantity of free acid be used in preparing the sensitising bath, difficulties will be experienced. To secure a satisfactory bath, a good sample of potassium bichromate should be taken, and liquid ammonia added, drop by drop, until the solution changes to a light orange colour, due to the formation of a double chromate of potassium and ammonium. The neutral bath will work well for a considerable time, but if used for a few prints and put aside for some months, it will deteriorate more or less. A standard sensitising bath is a 4 per cent. solution of bichromate of potash and ammonium, in equal parts, or bichromate of potash converted into a double chromate of potassium and ammonium. The tissue should be cut somewhat larger than required in the finished print, placed in the bath, face upwards, any airbells that may form being removed with a brush passed over the surface. The tissue is then turned face downwards in the

* A condensed report of a demonstration given before the Royal Photographic Society.

bath, and the back also brushed. Three minutes' immersion in the sensitising bath is sufficient, the temperature being about 50 deg. to 60 deg. F. The tissue must not be allowed to float or curl above the solution, nor adhere to the bottom of the dish. It is then placed upon a clean zinc-covered board, and squeegeed evenly and gently with a sufficiently wide flat squeegee, in order to remove excess of solution from the paper. Vigorous squeegeeing is not necessary, and will lessen the rapidity of the tissue. The tissue is then laid face upwards upon a blotting board and allowed to dry for five or six hours in a temperature not higher than 65 deg. F., or in a current of warm, dry air. A proper drying cupboard is desirable, but the drying can be effected in an ordinary room, care being taken to exclude fumes of gas or the products of combustion. In its wet state the tissue is insensitive, but as it dries it becomes sensitive, and must therefore be protected from the faintest rays of white light. Incandescent light will affect the tissue if allowed to reach it for any length of time at a short distance; but ordinary gas light has practically no effect. Another method of sensitising, which is strongly recommended when a properly ventilated drying cupboard is not at one's disposal, is the following:—A piece of plate glass is thoroughly cleaned with hydrochloric acid, well washed with water, dried, polished with powdered talc, and lightly dusted. Instead of squeegeeing away the excess of sensitising solution on the zinc-covered board, the tissue is placed face downwards upon the polished surface of the glass, and lightly squeegeed into perfect contact. Any moisture remaining upon the back of the tissue should be removed with a cloth, otherwise unequal sensitising will result. A good surface resembling patent leather in appearance, which gives good contact with the negative, and better results when fine detail is required is obtained by this method, which is very useful for miniature work upon ivory. The tissue takes longer to dry upon glass than in the ordinary way, but if placed in a current of air at a temperature of about 65 deg. F., it will be ready in eight or nine hours. If difficulty be found in keeping the tissue from white light during drying in this way, the glass on the opposite side to the tissue may be painted with an opaque substance, or covered with black paper, when the tissue may be dried in daylight.

The printed image is practically invisible, and it is necessary to use an actinometer to determine the exposure. The tissue is rendered insoluble in water in varying degrees, according to the gradations of the negative, by the action of the light. The more soluble portions are washed away by the application of warm water. For the support, a good paper, such as Whatman's is prepared with a substratum of gelatine. The surface of the paper may be smooth and shiny, when the print is required to possess the brilliant richness or the sheen characteristic of the carbon print; or a matt surface can be obtained, especially with the new matt tissues. The conditions of drying also affect the surface considerably. For single transfer the paper is coated with a mixture prepared as follows:—

Nelson's opaque gelatine	1 oz.
Water	20 oz.
Chrome alum	15 grains.
Water (warm)	1 oz.

The gelatine is soaked in water for several hours, until quite soft, heated on a water bath, and vigorously mixed with—

This mixture is then laid upon the surface of the paper with a broad camel-hair brush. Rough paper should have two coats of the solution, the second after the first is dry. The brushing should be first in one direction and then across, to ensure an equal coating. Paper thus coated keeps almost indefinitely if preserved perfectly dry; before being used for the development of a print it simply requires soaking in cold or tepid water for about one hour. Rough papers require longer soaking, but as an alternative the temperature of the water may be raised

to 150 deg. or 200 deg. F., when a short soaking will suffice. Care should be taken to remove any air-bells that may form upon the tissue when placed in the water, and also upon a single transfer paper; and when the tissue has been arranged upon the transfer paper and squeegeed in contact with it perfectly, it is placed, under slight pressure, between the blotting boards. It was pointed out that tissue dried upon the glass would not curl much in the water during the soaking previous to mounting in contact with the transfer paper; and that should never be allowed to curl in the opposite direction. Re-sensitised tissue will curl more than tissue dried in the ordinary way; and when the support is rough or thick it requires more vigorous application of the squeegee than when smooth or thin papers are used. Care should be taken not to allow the tissue to remain in the water too long, or frilling of the edge or difficulties in mounting may follow. The print should remain under pressure between the blotting boards for at least twenty minutes, or, if very rough paper be used, half an hour or forty minutes will not be too long.

The sensitising bath recommended in the case of thin negatives is of 2 per cent. strength; negatives of medium density require a 4 per cent. bath; while very strong and dense negatives require a 6 per cent. bath. It is possible to work with baths as weak as 1 per cent. and as strong as 8 or 10 per cent., but they are not recommended on account of their tendency to work indifferently. It has been recommended that tissues, required to be of different sensitiveness, should all be sensitised in the same bath, and allowed to remain according to the degree of sensitiveness required. This method, however, is less satisfactory than that of different baths of various strengths. When the bath shows signs of fogging it should be rejected; and if it becomes acid it should be neutralised with ammonia. A properly-made bath should work well for a month or two.

The developing is a simple matter, provided the previous operations have been properly carried out. The water should be heated to about 100 deg. F., and it should be unnecessary to greatly increase the temperature afterwards. If, however, the exposure has been very long, it may be necessary to raise the temperature to 110 deg., 120 deg., 130 deg., or even 140 deg. F., but an over-printed tissue is best developed at about 120 deg., plenty of time being given, instead of forcing by higher temperature, with which the risks of blistering or frilling are increased. Over-exposure may be corrected by the addition of a little ammonia to the water, but care must be taken or blistering and frilling will ensue. A few minims of a 2½ per cent. solution of sodium hydate in a little water applied with cotton wool will be found to work well for local development, or, added to the developing water, to cause more general reduction. Too much sodium hydate, however, causes blistering. If the gelatine appears to be dissolving quickly, with a loss of detail in the high lights, the temperature of the water should be reduced to about 90 deg. or 85 deg. F., and development carried on more slowly. By reducing the temperature of the water a much under-exposed print that would be spoilt by water of a higher temperature can often be saved. Development is better commenced at a temperature of 90 deg. or 95 deg. than 100 deg. F., because, when commenced at high temperature, there is danger of washing away the delicate parts of the print. A word of warning is necessary again using a wet blotting board for placing the prints between after mounting and before development, as this is frequently the cause of dark markings upon the print. The greater the delay of the printing the more soaking in the water at 90 deg. or 100 deg. is required before stripping the tissue. Stripping too soon is apt to cause blistering or frilling, but if one end happens to get broken or frilling commences, it is a good plan to leave that end and start stripping from another. While developing it is advisable to have another bath of cold water at hand,

which to plunge the print at the right moment, to stop further development.

The various coloured tissues necessitate somewhat different fitting—for instance, a red chalk tissue requires much more tinting than black or a dark brown.

The chief causes of failure are found in the insolubility of the tissue. This may be due to free acid in the bichromate of potash; too long drying of the tissue; the action of gas fumes the products of combustion; the action of white light when the tissue is dry, or almost dry; the tissue being dried in a damp atmosphere; too long keeping of the tissue after sensitising; or, of course, over-exposure. Unlike most other printing papers, a little white light falling upon the carbon tissue, before, or in the course of printing, is apt seriously to affect it; for in the carbon process we have to guard against the continuing action of the light. A small amount of light upon the surface of the tissue, either before or after exposure, will continue its action in the dark, and in a few hours produce total insolubility upon the surface. This continuing action of light might be utilised in under-exposure, caused, say, by unexpected failing of the light. In such a case the print should be placed in a box or drawer, protected from white light, and allowed to finish in the dark; eight or ten hours there was the slightest moisture about being enough perhaps to finish it. In addition, however, to the continuing action of light there is a lateral or spreading action; and a print taken from the frame and allowed to continue printing will not, therefore, show such delicate and fine detail as when development is started directly after exposure in the frame. Development should always be full; all soluble gelatine should be washed away, otherwise there may be a want of fine detail or murring and the print may show unequal depths. The surface of the print should not be touched with the fingers during development; but a flat print, one lacking brilliancy, may be improved by applying cotton wool to the high lights, to increase them. Shadows when too deep may also be reduced by rubbing the cotton wool over them. Slow drying of the print tends to give a more matt surface than rapid drying; and if laid upon blotting paper, and dried for about twenty-four hours, the print will be more "flat" than if it be dried quickly, whilst a print dried by heat will show more brilliancy in the shadows. Reticulation, or a series of blisters all over the print, is a peculiar difficulty, which may be caused by some of the defects already mentioned. A common cause of reticulation is the use of water at too high a temperature. If new tissue suffer by the washing away of the high lights, it will be found to improve by keeping for a few days.

After development, the print is transferred to cold water and then to a 5 per cent. solution of alum to harden the gelatine and fix the print. The alum also helps to increase the permanence of the print, and to remove any colour which may have been imparted to the paper by the chromic salts. The prints should be allowed to remain in the alum bath for ten minutes or a quarter of an hour, but, if they still show colour from the bichromate salts, they may remain longer in the alum. They should then be washed for about ten minutes in running water, and hung up to dry (the best way is to suspend the prints on a line to dry, not to blot them); after which they can be mounted in the usual way. Difficulties due to frilling may be found if the print be immersed too long in the water before being brought into contact with the support; when the safe edging has been imperfectly performed, or if it be done upon the film side of the negative instead of the glass side. Frilling may also be due to unequal squeegeeing; to the tissue being under pressure for too short a time, or to the water being too hot at the commencement of development.

Then comes the work which few prints do not require, namely, potting or touching up. The best way to do this is to make a little solution of gelatine mixed with some of the same

coloured pigment as that in the print and work it on to the print through an air brush. It is not advisable to use much colour in the brush; and, of course, it is necessary to keep the gelatine solution warm while using it. If this part of the work be done carefully no objection can be raised against it; but when a brush is used some artistic skill is, of course, required.

In the double transfer process a thick paper is first coated with hard gelatine, quite insoluble, to act as the temporary support. This is treated with waxing solution, made as follows:—

Yellow resin	3 drams.
Pure beeswax	2 drams.
Turpentine	10 oz.

A little of this solution is taken upon a flannel and rubbed in a circular motion over the surface of the temporary support. Then the surface is polished, and about an hour allowed for the spirit to evaporate. The waxed temporary support is then placed in the mounting water and after a few minutes the exposed tissue is also placed in the mounting water; it is then squeegeed into contact the same as when mounting a single transfer print and developed as previously shown; after stopping development with the addition of cold water the print is placed into the alum bath, care being taken that the print is soaked long enough for all discoloration from the bichromate solution to be removed from the temporary support before the print is transferred to the final support. The washing then has to be continued until the print is free from alum, and the print dried before transferring to the final support. If the print be not dried at this stage there is a danger of the image being blurred. Afterwards the tissue is soaked for a short time in cold water, and transferred to the final support, which is best when smooth, rough paper not being nearly so suitable. The final support should be previously placed in a 2½ per cent. alum bath for at least half an hour, and then placed in tepid water with the print upon the temporary support. The final support should be a little smaller than the temporary support, but a little larger than the print. The print is brought into contact with the final support under the water and then well squeegeed into contact upon the zinc-board. The prints are then blotted off and hung up to dry.

Difficulty is sometimes experienced in bringing the dry hard tissue into perfect contact with the negative in the printing frame; but if both be placed in the frame, and if the tissue be allowed to lie upon the negative for ten minutes without pressure from the springs, it will be found that better contact can be secured. The printing should always be carried on in diffused light.

Ivory and opal work should be done by double transfer, although the latter may be done by single transfer. Care should be taken that the opal is absolutely clean. The print is developed upon a waxed temporary support, and, when dry, transferred to a piece of smooth ivory, treated with a solution of—

Nelson's opaque gelatine	½ oz.
Water	10 oz.

The gelatine is first washed and soaked and dissolved by raising the temperature of the water, when it is filtered through a piece of linen or muslin. The following is then added:—

Chrome alum	6 grains.
Water (warm)	½ oz.

and the mixture is well stirred.

The ivory should be placed in a warm dish, and the warm solution poured upon it. The print is adjusted upon the ivory; squeegeed from the back of the print upon the temporary support into contact, and hung up to dry, after which the support can be stripped off, leaving the print upon the ivory. It should be noted that, although the high lights on the print when wet may appear quite white, they may show a distinct tone when the print is dry.

The only objection to the use of chromate of ammonium instead of the potassium bichromate converted into a double chromate of potash and ammonium is its expense, the latter being very easily made in solution and cheaply. It is not advisable to put the tissue under great pressure, as suggested, with a view to hastening the drying between mounting and development. A better plan would be to use only slight pressure for a short time and then facilitate the drying by placing the mounted tissue in a current of warm, dry air.

JOHN H. GEAR, F.R.P.S.

Exhibitions.

PROFESSIONAL PHOTOGRAPHY AT DERBY.

THE normal aspect of the interior of the Corporation Art Gallery at Derby was considerably altered last week, and the janitor at the door was bemoaning the lack of colour and glaze and gold frames, and "suspected" that the aspect of the more sombre show of pictures on view was responsible for the fact that the inhabitants of Derby were not flocking in their thousands to view the exhibition of pictures by the Professional Photographers' Association. Be it whispered, however, that the said janitor was more or less right when he designated the show as a "bit dull an' all," and we trust that the members of the Convention who visited the exhibition did so with an open mind and a complete ignorance of the two exhibitions round the corner, of work by American professionals, as exploited by the Platinotype Company and Kodak, Limited.

Not that one wishes to make odious comparisons. The trend, characteristics, and styles of the two classes of workers on either side of the "herring pond" are too diverse to admit comparisons, and each possesses both its giants and its dwarfs. Possibly, too, the American exhibits were more representative than the English, but the fact remains, the exhibition at the Derby Art Gallery, although containing works by such eminent workers as Wm. Crooke, Harold Baker, Frederick Hollyer, Ralph Robinson, T. Lee Syms, and other well-known men, was as a whole distinctly dull. One's first impression on entering the room was that of oppression—not the kind of oppression experienced by the anti-gummer on his first visit to the Salon, but more the oppression occasioned by lack of something fresh, and one instinctively asked oneself, "Is this a representative show of English professional photography?" A glance at the catalogue, which contains but twenty-two names of exhibitors, convinces us that it is not; whether this is due to the lack of interest taken by the English professionals in the work of the Convention, or whether time or other circumstances did not permit a gathering together of a greater number of works, we do not know, but the general effect seemed to be that in many cases the English professional had endeavoured to emulate the amateur at the provincial show, instead of exhibiting his best work as supplied to his customers. One seemed to know that the pictures shown by the aforesaid Americans were replicas of those dispensed among their clientèle in the ordinary way of business—picked specimens, no doubt, but still ordinary straight work. The bulk of the English pictures, on the contrary, created just the opposite idea. They struck us as being pictures produced in most instances, with an effort, for exhibition purposes, and distinctly not indicative of the everyday work of the professional photographer as known to the purchaser of his photographs, which is surely what we desire to ascertain, and which should be made quite clear in an exhibition of this character. The pictures, too, were hardly done justice to by the rather depressing chocolate-coloured matchboarding covering the walls on which they were hung. Surely the exhibition was worth a little adornment in the way of hangings, especially as the room was so splendidly lit both by day and in the evening.

To the visitor, the works of Wm. Crooke, of Edinburgh, immediately claimed attention as quite the finest specimens of portraiture in the room. These pictures have a dignity all their own, and doubtless impressed the visitor at Derby as much as they did at the House Exhibition at the Royal Photographic Society. If one were inclined to be capitious, exception might be taken in some instances to the lettering in imitation of titling on an old steel engraving. The idea is excellent, but when in some cases, as particularly in No. 79 (William Downey) the portrait itself is slightly

blurred, possibly by movement of the sitter, the whole effect is ingruous. Mr. Lee Syms exhibited a good selection of his quiet good portraiture. As specimens of clean, unemotional work pictures are in the very best taste, as well as being technically excellent.

Harold Baker's three exhibits are rather disappointing. No. "The darkened roof rose high," does not rise beyond the ordinary architectural study, and the texture of the stone has been spoiled by giving it quite another texture, i.e., that of bolting. No. 102, "Miss Lily Hanbury," has always been successful, this particular print struck us as rather poor in quality. John C. showed many old friends that have appeared at various provincial exhibitions. He has evidently made "genre" take an important place in his profession.

C. and F. Dereské are local photographers who show some excellent work. No. 87, "On the Canal," is practically the only picture pure landscape in the room, and it was well worth looking at a second time. The work of Messrs. Dereské throughout the show is characteristic, inasmuch as it is bold, clean, and straightforward. No. 88, a portrait of an Indian cricketer batting, being full of action. Frederick Hollyer showed several of his well-known examples of copying work. Martin Jacollette had one or two big things in portraiture, notably No. 55, "Madame Sassard." We wonder if this is direct work?

Ralph W. Robinson's "Child Reading," No. 63, is good, and other works show knowledge effectively applied. John C. Spiers' pictures are also noteworthy, being restrained in tone, and well framed; No. 56, "Miss ———," was particularly noteworthy. We wonder why H. H. Chapman sent No. 66, "Shrimps," as an example of professional work? These two enlarged snapshots hardly likely to make a splash. Messrs. Alfred Ellis and Walter "George" Alexander as François Villon" was rather hot, but apparently an ordinary print stained red. The technique is splendid, however. R. Fellows Willson had two of his dainty portraits, which were as good as anything of their kind in the exhibition, and I. Connell's work was also distinctly clever. There were other good things on view, but also much that was unworthy, and but for the sprinkling of really good pictures here and there, the exhibition would have to be marked down as mediocre only.

FORTHCOMING EXHIBITIONS.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.

September 16 to November 5.—Photographic Salon, Dudley Gall, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Fortieth Exhibition, New Gallery, Regent Street, London. Secretaries, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. sec., H. Hemmingway, Tooker Road, Rotherham.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretaries, L. C. B. Appleby, Barnbygate House, Newark.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Secretary, James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Argent, 55, The Drive, Hove.
 November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., W. Simmers, Aberdeen House, Ramsgate.
 December 2-8.—Southsea Photographic Society. Hon. Secretary, J. Lawton, 20, Clarence Square, Gosport.
 December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.
 December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
 December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.
 December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.
 January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, V. A. Frame, 28, Bank Street, Hillhead, Glasgow.
 January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, Michell, 180, Browning Road, Manor Park, E.
 January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.
 February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.
 June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Scott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 1.—"Photographic News." Quarterly Competition. Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.
 October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
 October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Union Allegre and Co., 59a, New Oxford Street, London, W.C.
 October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.
 October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
 November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.
 December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.
 March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

New Book.

Bibliothèque Photographique." Manuel Pratique de Photographie sans Objectif. L. Ronyer. Gauthier-Villars, Quai des Grands-Augustins, 55, Paris.

In this small volume M. Ronyer has very ably put forward the claims of the pinhole as a substitute for the lens. Those, who find artistic attractions in photographs taken under the simple optical conditions this method implies, will find much that is useful in the book. Never yet have the conditions been more favourable for pinhole photography. We have dry-plates of extreme sensitiveness, that the exposure may not be tediously long for some subjects, and printing papers are to be had in such variety that it is an easy task to find one which is peculiarly adapted to the wants of the negative. We fail to follow the author in his claim for a wide applicability of the pinhole process, as stated in the preface. This may depend upon difference in appreciation of pictorial beauty, and we must leave the question to be decided by time. The charm of the pinhole photographs lies in its suppression of small detail. But this is a limitation, which must be accepted, whether desired or not. On the other hand the prolonged exposure is a serious drawback.

LIGHTING THE SITTER.

PORTRAITURE has come to be something more than the professional usual thing. Time was when the amateur looked askance and doubtfully at the taking of the human face divine, and confined his labours to landscape work; but nowadays he is teaching the professional a new departure, and all manner of artistic effects are the outcome of his endeavours at posing and lighting, and effects are produced which make the old-fashioned professional shut his eyes with holy horror, however much the artist may laud. But what is it the reasonable man, professional or amateur, who is not amuck for bizarre effects, desires in a well-illuminated head?

In a recent issue of "The Camera" Mr. J. Bartlett states that the problem to solve is how to get the greatest amount of gradation combined with perfect relief in the model and with the shortest amount of exposure? These desiderata may be had in any kind of a studio, and we do not think it at all necessary to have recourse to extraordinary methods of illumination. Indeed, it always seemed strange to me why the photographer should go to the expense of having a great expanse of light, and then cover it almost entirely up with opaque curtains. The first requisite toward obtaining anything you want is, first of all, to know what you want. If a photographer cannot tell by looking at a face whether it is illuminated artistically, all the monkeying with curtains would not give him (unless by accident) an effective picture. He may hit it by accident, but then, ten to one, he will not know it until some appreciative friend digs it out of the waste basket and labels it for the Salon.

To know when a head is properly (artistically) illuminated, one must train oneself to observation of faces and comparison with works of painters; that is, he must accustom his eye by watching outside the studio what is beautiful and then try to repeat it under the skylight. For, after all, the studio or skylight is only vade mecum of the photographic artist. It is one of his moulding tools for making pictures which shall please the eye which is not used to living under a skylight. The most successful photographer is he who best succeeds this way. The advantages of a well-constructed skylight are that we have the agent under better control for securing every desired effect than we have in our ordinary room or out of doors. In the ordinary dwelling room or out in the open we may produce what we want, but with greater trouble than under the skylight.

When, through observation outside the studio, we see some effect of light and shade which strikes us as charming, we ought to analyse, as far as possible, the cause. A good deal of training of the eye is necessary to secure good effect in photography. Experiments with lighting of marble or plaster busts in lieu of the human face is something quite different from the illumination of human tissue. The marble bust under certain conditions seemed to possess wonderful delicacy, as well as relief, and when the human head is placed under like conditions it, too, seemed to look as lovely; but, photographically, the delicacy was not in it.

The high lights and the next adjacent lights are rendered beautifully in the negative, but its deep shadows and those allied to them are far too heavy for photographic purposes. Where the photographic subject is a blonde, with flaxen hair, and her garments some of white, light fluffy material, the relationship to the semi-transparent marble is closer, so that the sculpture lighting is in such cases effective. There is enough light carried into the shadows by reflection from the white drapery to soften, while the character of the lighting employed gives enough relief. Even in a well-lit living room most of us have noticed the fine effect produced by a lady, dressed in diaphanous material, seated near an open window. Put a black-bearded man with a swarthy complexion and a suit of black clothes and a boiled shirt, in the same position, and note the effect.

Mr. Felix Raymer has given some most excellent suggestions to "The Camera" readers for employment of ordinary room light, and we would suggest to pose some of your fair-complexioned lady friends, dressed up in soft white material, seated near a lofty side window (like some of our old-fashioned high-ceiling houses have), the lower portion of which is covered with a semi-transparent material, a suitable system of reflectors being used to carry light into the deepest shadows; but be careful not to overdo the reflections—just enough to lessen the contrast. All over you are aware of the flatness of outdoor exposure. With light acting all around, there can be no relief, or next to none. But you can get the same results, and some photographers get nothing else in the best-appointed studios. Flatness is just as easy to get in

a studio with unrestrained illumination as it is out in the open. But it will be good practice, in the meanwhile, for the photographic novice to look about him and study faces as he sees them in the street cars, the theatre, or at his own home.

AN ACID-PROOF TABLE TOP.

THREE or four years ago the writer saw in a pharmaceutical journal a formula for a black finish for table tops. The article did not give the author's name nor the original source of the formula, but stated that the method was "used abroad." Further acknowledgment cannot, therefore, be made. The formula was as follows:—

I.	
Copper sulphate	1 part.
Potassium chlorate	1 part.
Water	8 parts.
Boil until salts are dissolved.	
II.	
Aniline hydrochlorate	3 parts.
Water	20 parts.
Or if more readily procurable:—	
Aniline	6 parts.
Hydrochloric acid	9 parts.
Water	50 parts.

By the use of a brush two coats of solution No. 1 are applied while hot; the second coat as soon as the first is dry. Then two coats of solution No. 2, and the wood allowed to dry thoroughly. Later a coat of raw linseed oil is to be applied, using a cloth instead of a brush, in order to get a thinner coat of oil.

The writer used this method upon some old laboratory tables which had been finished in the usual way, the wood having been filled, oiled, and varnished. After scraping off the varnish down to the wood, the solutions were applied, and the result was very satisfactory.

After some experimentation the formula was modified without materially affecting the cost, and apparently increasing the resistance of the wood to the action of strong acids and alkalis. The modified formula follows:—

I.	
Iron sulphate	4 parts.
Copper sulphate	4 parts.
Potassium permanganate	8 parts.
Water, q. s.	100 parts.
II.	
Aniline	12 parts.
Hydrochloric acid	18 parts.
Water, q. s.	100 parts.
or	
Aniline hydrochlorate	15 parts.
Water, q. s.	100 parts.

Solution two has not been changed, except to arrange the parts per hundred.

The method of application is the same, except that after solution No. 1 has dried the excess of the solution which has dried upon the surface of the wood is thoroughly rubbed off before the application of solution No. 2. The black colour does not appear at once, but usually requires a few hours before becoming ebony-black. The linseed oil may be diluted with turpentine without disadvantage, and after a few applications the surface will take on a dull and not displeasing polish. The table tops are easily cleaned by washing with water or suds after a course of work is completed and the application of another coat of oil puts them in excellent order for another course of work. Strong acids or alkalis when spilled, if soon wiped off, have scarcely a perceptible effect.

A slate or tile top is expensive not only in its original cost, but also as a destroyer of glassware. Wood tops when painted, oiled, or paraffined have objectionable features, the latter especially in warm weather. Old table tops after the paint or oil is scraped off down to the wood take the above finish nearly as well as the new wood.—"Journal of Applied Microscopy."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July	Name of Society.	Subject.
25.....	Southampton Camera Club	Developers and Development. Debate.
27.....	North Middlesex Photo. Soc.	Playtype. Demonstrated. Mr. S. E. Puddy.
28.....	Watford Camera Club	Competition—"Sunlight and Shadow."

Commercial & Legal Intelligence.

At a public auction sale at 66, Farringdon Street, on Wednesday 27, at 12.30, over 100 cameras, lenses, and other accessories to be sold without reserve. On view Tuesday previous, 1 to 5 p.m. Catalogues on the premises, and of the auctioneer, J. Theodor Albemarle House, Hounslow, London, W. A good chance is offered to anyone desirous of "picking up" some cheap apparatus.

CHROMO Syndicate, Limited.—The above-named company has registered with a capital of £100 in £1 shares. Object, to carry the business of manufacturers of and dealers in speaking apparatus, pictures, and all machinery and tools for making the same, mechanical engineers, manufacturers of and dealers in machinery and apparatus of any kind, etc. No initial public issue. The signatories appoint the first directors. Qualification, two shares. Remuneration as fixed by the company. Registered office, 59, Moorgate Street, London, E.C.4.

YEATES and Son, Limited.—The above-named company has registered with a capital of £5,000 in £1 shares, for the purpose of leasing, purchasing, or otherwise acquiring the business of optical money-lenders, or otherwise acquiring the business of optical money-lenders, now carried on by Arthur Mitchell Yeates and Son, at 2, Grafton Street and 33, Nassau Street, Dublin, and the business of optical money-lenders, etc., now carried on by Percy C. Curtis under the title or firm of Curtis Optical and Photo Company, at Dawson Street, Dublin, and amalgamate the two businesses. Directors, not less than two more than seven, the first being Messrs. Arthur Mitchell Yeates, Arthur Yeates, and P. C. Curtis. Registered office, 2, Grafton Street, Dublin.

CINEMATOGRAPH LOSSES. At the London Bankruptcy Court Thursday last, before Mr. Registrar Hope, the first meeting of creditors interested under the failure *re* Oscar Lotinga, professional known as "Oscar Luck," was held. It appeared that the petitioner was filed against debtor in bankruptcy by Messrs. Fieldings, Limited, money-lenders, of Cardiff, creditors for £95. The debtor had been a troupe known as "The Six Bros. Luck," for the past twelve years, and two years ago he left the troupe and commenced touring with cinematograph entertainment, but within a few weeks he had to leave it, owing to the heavy losses he made. He estimated his liabilities at about £600, and assets nil, and alleged his failure to have been caused through loss in connection with the cinematograph exhibition referred to. Eventually the estate was left in the hands of an official receiver for summary administration in the usual manner.

At the Bromley County Court on Friday, Mr. Cooper, the landowner of the Railway Hotel, West Wickham, sued Mr. Bullock for £12s. the price which he charged for a photographic enlargement. Holroyde appeared for the plaintiff, who said that the defendant, who at his house, asked him to make the photographic enlargement question. About a month after, when the question of payment was referred to, the defendant told him that the said enlargement was present, and that no charge was to be made. The defendant's agent brought the photograph back and said that he could keep it, but replied that he would not have it. The defendant stated that Mr. Cooper now had the photograph. It was denied by Mr. Cooper that the photograph had been returned; but his Honour directed that there should be a non-suit. Later in the day, however, this judgment was set aside by his Honour. Immediately the decision had been given, Mr. Cooper despatched a messenger to the defendant's house and the photograph in question was given to him. This messenger, Charles Steven Lane, stated that he went over to Mr. Bullock's house to fetch the photograph produced. The servant gave it to him. The judge said that it was a serious case of perjury, and the judgment must be set aside, as the plaintiff may have suffered injustice. All he could do that day, however, was to order the case to be restored to the list. There was no doubt a frightful amount of perjury committed in the County Courts, and an example would, perhaps, have a beneficial effect.

RE Charles James Angel Gunn, photographer, lately carrying on business in co-partnership at 2, The Quadrant, Richmond, and 1, Sloane Street, S.W. This debtor made an application for his discharge at the London Bankruptcy Court on July 7, before Mr. Registrar Hope. Mr. Chapman, official receiver, reported that receiving order was made on the petition of creditors early in 1903, the public examination was concluded in May of that year. The debtor filed a statement of affairs, showing liabilities expected to reach

inst the estate for dividend amounting to £2,303 10s., and the assets were estimated to produce £4,945 11s. 11d. The trustee of the estate, Mr. Percy Estcourt Metzner, of 40, George Street, Richmond, reported that the proofs lodged amounted to £2,320 15s. 3d., and the assets would probably realise £142, so that there was no probability of any dividend being paid to the unsecured creditors. The debtor, in estimating the amount of his assets, returned the sum of £1915 as being the estimated surplus of the value of his house in Sheen Road, Richmond, after paying off the mortgage, and the interest on the partnership business, after deducting the charges thereon, but the surplus had not been realised. The bankrupt in 1886 purchased £1,000 a photographer's business at 2, The Quadrant, Richmond, to be paid by instalments. He then entered into partnership with his brother-in-law, and they jointly carried on the business. Their capital at the time consisted of £456 given them by relatives. In 1896 they also acquired, for £450, a branch business at 162, Sloane Street, W., and the partners carried on both businesses together until May, 1902, when, in consequence of disputes between them, the debtor's partner commenced an action against him for the dissolution of the partnership. The debtor's failure has been caused not through business, but from the extravagant expenditure he incurred in respect of the private house built to his order in Sheen Road, Richmond. Mr. Lickfold, who appeared on behalf of the debtor, argued that the debtor's assets were sufficient to pay 10s. in the £. The partnership business had been sold for £4,850, and after deducting partnership debts there remained a sum of £2,797 for division between the partners, so that the debtor was entitled to about £1,400. The Registrar said the discharge would be suspended for two years, with liberty to apply to vary the order if the assets realised more than 10s. in the £, on the amount of the unsecured liabilities.

News and Notes.

The first specimen of the new Lumière process of colour photography, as described in our issue for July 8, was shown at the Derby Convention by Mr. P. K. Grant.

Mr. J. W. WRIGHT has taken over the hon. secretaryship of the Sheffield Photographic Society. His address is 62, Vale Road, Sheffield.

LONDON and Provincial Photographic Association.—On Thursday, July 23, a lantern lecture will be given before the members of this Society by Mr. A. L. Henderson entitled "Athens: Its Monuments and Palaces." Visitors are invited.

HER Royal Highness Princess Christian of Schleswig-Holstein made a visit to Messrs. Langnier's studios, at 23a, Old Bond Street, this week, and M. Langnier had the honour of photographing her Royal Highness.

Mr. EPSTEIN, of 48, Great Hampton Street, Birmingham, has just started business in the wholesale moulding, picture frame, glass, and mount-cutting line. We understand that frame making for photographers will be one of his specialities.

THE Austin-Edwards Monthly Film Negative Competition.—The best camera for current month has been awarded to George C. Morgan, of 15, Anerley Park, Surrey, for his negative, "Ludgate Circus and Paul's."

A CERTAIN photographer called the other day on Messrs. Chas. Lummernann and Co., of St. Mary-at-Hill, in reference to their new mount paper, which is developed with the aid of fine sawdust. He stated that he had tried the paper, but had spent hours dissolving the powder developer (1) in hot water.

AN interesting group of pictures, designated as "History Photos," exhibited in the British Section of the Liberal Arts Building at the World's Fair. The Photographs cover the four walls of one of the galleries or rooms of the section, and form a pictorial view of British history and customs in England.

MUCH of the success of the Derby Convention is due to the efforts of the local executive, who worked untiringly to make things go. The indefatigable local hon. secretary, Mr. W. Crowther, was particularly to the fore, and a special meed of praise is due to him and his daughter, Miss Crowther, who assisted her father materially.

WEST London Photographic Society.—As the excursion to Dedham (notified to be held on July 30) has fallen through owing to lack of hotel accommodation, it has been decided to hold an outing to Hayes Common on August 6. All intending to be present should communicate with the Hon. Sec., F. C. Hart, 37, Willcott Road, Acton Hill, W.

MR. JONES, photographer, of Northgate Street, Gloucester, is exhibiting in his shop window a mark of his enterprise in the shape of a photograph embracing the whole landscape between May Hill and Bredon Hill, in the valley of which lies the City of Gloucester. The photograph measures about 36in. in width and 15in. in depth, and was taken in three sections from Robinswood Hill.

CONGRATULATIONS to Mr. R. J. Kindon, the popular hon. secretary of the London and Provincial Photographic Association. He has just been made a proud papa. The new arrival is a boy. We can in fancy see him expounding to a future generation of the L. and P.'ites the latest intensifier, or a sure cure for pinholes, and a new method of time development, while the inevitable oldest member tells him, "I did all that before you were born, my boy."

A PROCESS Exhibition.—The recent collection of engravings opened for some time at the Victoria and Albert Museum, South Kensington, will be followed in October by a loan exhibition of photo-engravings in monochrome and colour. All who are practically engaged in the work, or who may have examples of technical or historical interest, should communicate with the South Kensington authorities. The space at disposal for the exhibition being limited, applications to exhibit should be submitted without delay.

"LA Photographie Artistique."—Under the title of "La Photographie Artistique," M. Annibale Cominetti will shortly produce an illustrated publication dealing with matters photographic. Well-known writers on the subject will contribute articles, and the illustrations will pass before a committee composed of artists and sculptors before being inserted. The articles will be printed in French and Italian, and the subscription is 10s. per annum. All letters and inquiries should be addressed to M. Cominetti, 12, Rue Finanze, Turin, Italy.

CINEMATOGRAF of Executions.—Visitors to the St. Louis Exhibition, says the Hong Kong "Daily Press," will shortly be able to witness a novel succession of cinematograph pictures portraying the execution of 200 prisoners at Canton. A short time ago a Hong Kong photographer paid a visit to the Viceroy, and came to an arrangement with him whereby all executions were to be postponed until a date towards the end of the present month. A cinematograph was meanwhile on its way from the United States, and is now in the colony awaiting transhipment on its gruesome errand.

INCOMBUSTIBLE Celluloid.—It is reported that two Frenchmen, MM. Mabillo and Lerclerc, have patented a process for making a kind of celluloid which is incombustible. To a solution of celluloid is added a mixture of ether and alcohol containing iron salts. A clear liquid of the consistency of syrup results, and if the solvents are driven off from this, an incombustible non-inflammable celluloid remains. It would appear from the announcement that a chloride of iron is used, since it is stated that should the celluloid become heated the gases of the chlorine components would extinguish the flames. The material can be worked as easily as ordinary celluloid, and it is thought that it will be valuable in the manufacture of electrical apparatus. Its application to photography is obvious.

DR. ISAAC ROBERTS, the well-known astronomer, died suddenly on Sunday at his residence, Starfield, Crowborough Beacon, at the age of seventy-five. A large part of Dr. Roberts's life was devoted to science, in which he included practical investigations in geology, microscopy, spectrum analysis, astronomy, etc., carried on formerly

in Liverpool, but for the last thirteen or fourteen years at his residence at Crowborough, where he had a capably-equipped observatory. He was an expert in stellar photography, and was the inventor of a machine for measuring the magnitudes and positions of the stars. The results of his experiments have been published in the "Proceedings of the Royal Society" and in other scientific periodicals. In 1893 and in 1900 he issued two volumes of photographs of stars, star-clusters, and nebulae, with scientific deductions founded upon them.

THE Optical Convention.—It is proposed to hold an optical convention in London next year. At a meeting held on Monday last, in the rooms of the Society of Arts, Dr. R. T. Glazebrook, F.R.S., the president of the Optical Society, occupying the chair, an executive committee was elected, and the following were elected honorary vice-presidents:—Lord Crawford, Lord Rosse, Lord Rayleigh, Lord Blythwood, Sir William Abney, the Hon. Alban Gibbs, Mr. W. H. M. Christie (the Astronomer Royal), Mr. T. R. Dallmeyer, Mr. J. Stuart, Sir Howard Grubb, Dr. Glazebrook, and Lord Kelvin. One of the honorary vice-presidents will be asked to take the position of president of the convention. The chairman said that it was proposed to hold in conjunction with the convention an exhibition of optical goods. It was hoped that the exhibition would be representative of the British optical trade as a whole, and one in which all firms would co-operate as far as possible. Some discussion ensued with regard to the date, which one member of the committee suggested might be April or May of next year, but the matter was eventually referred to the executive committee.

SURGICAL Photography.—Cinematograph records are now made of all operations performed by a certain physician and surgeon in Paris. The latter entered some time ago into an arrangement with an artist of the bioscope, who has taken pictures for the doctor on several occasions. It is stated that the records in question are invaluable as scientific documents. One of the surgeon's operations which had been cinematographed was that by which the link of flesh connecting the Mindu twins, Radica and Doddica, was severed, and which was pronounced to have been a remarkable success, though, to be sure, both twins died of it. The famous doctor has now fallen out with his photographer in ordinary. Having looked in at several fairs, the surgeon found that mutoscope views of operations of all sorts performed by him, from common bone sawing to delicate cases of trepanning and laryngotomy, were being exhibited in the chambers of horrors side-shows at ten sous for grown-ups, children under fifteen half price, those under ten not admitted. The doctor is accordingly bringing an action against the photographer for infringement of a new kind of copyright. He argues that the defendant has no right to make use of the records of cinematograph pictures without his consent, as the proprietary rights belong in a great measure to the surgeon who performed the operations and thus supplied the subject of the views.

THE Print Portfolio Secretary (Mr. W. H. Atkinson) of the Yorkshire Photographic Union has just returned the loan prints which have been circulating among the societies in the Federation during the last half of the winter session in the form of a portfolio of invited work. The portfolio contained twenty-seven prints by the late H. P. Robinson, eight by Ralph W. Robinson, and fifty-six by members of the Postal Camera Club, of which Mr. W. R. Bland is the secretary, made up as follows:—L. E. C. Dapples (2), C. T. Holding (2), Walter Benington (2), Arthur Marshall (2), Hubert Waters (2), Dr. F. Graves (4), James Gale (2), P. M. C. Grove (2), F. J. Mortimer (2), John C. Warburg (2), Miss A. B. Warburg (2), Miss Bessie Stanford (3), Miss Hilda Stevenson (2), Mrs. A. O. Jennings (2), T. Lee Lyons (2), Dr. Barr (2), Dr. Crump (2), Percy Lewis (2), Hector E. Murchison (2), J. M. Whitehead (2), Rev. C. T. L. Barnwell (2), W. R. Bland (9). The names of the various workers will show the class of work lent and its educational value to the different societies. During the period named the portfolio has been shown at twenty-three societies' meetings, and at several conversations and larger gatherings, and has consequently been seen by hundreds of photographic workers. The heartiest thanks of every member of the Yorkshire Photographic Union are due to all those who have so kindly contributed copies of their work for the benefit of other workers.

WHAT Makes a Photograph Unfit for Publication?—The editor of "The Inland Printer" department was called upon recently to settle

a dispute between an advertising manager and the editor of a metropolitan newspaper. The question was as to the fitness for publication in half-tone of a photograph supposed to advertise a corset picture was of a most voluptuous woman, photographed in her wearing the corset over a specially short petticoat, while she was presumably fastening her slipper. A special effort had been in the woman's pose to make her anatomy from the bottom petticoat down the conspicuous feature of the picture. The editor decided against the reproduction of the photograph, and the advertising manager became furious. He demanded to know what was the rule that decided the unfitness of a picture for publication. Pictures, he said, were printed of South African women and aborigines almost nude, chorus girls, acrobats, trapeze performers; bathers in all manner of poses were printed. The object to his corseted woman? The exact dividing line between decency and indecency is not easily drawn, still an answer has been formulated to this advertising manager, and it was as follows: "Photographs of human beings in costumes or poses in which they would not appear in public are liable to be unfit for publication in an ordinary newspaper." This seems about as reasonable a definition of what makes a picture unfit for publication as we are likely to get.

BLUE Tones—A New Process.—A curious method of giving tone to a bromide print is communicated by Professor Namias, of "Das Atelier." It depends on the reduction of molybdenic acid to a more properly speaking, of an alkaline molybdate, for the acid is soluble in water to only a very slight extent. The compounds of molybdenum, like those of vanadium, present a whole series of colours, but few of them have hitherto been supplied in photographic processes. Professor Namias' procedure is not very complicated. He makes a stock solution of ammonium molybdate and mixes it with three times its bulk of water, adding thereto potassium bisulphite in the proportion of 22 grains per ounce (5 per cent). The print, after a brief immersion in water, is placed in this mixture and in the course of fifteen or twenty minutes, attains a violet tone with appreciable increase of intensity. Professor Namias does not claim technical perfection for the process with which, he says, it is difficult to preserve the high lights pure. The toning process takes place in these portions resists a thorough washing (with tap or pure water Professor Namias does not say) and is more efficacious; alkalis destroy the blue colour. The molybdate solution used in the above formula is made by dissolving 175 grains of molybdenic acid in 2 ounces of a mixture of strong acid and water. This solution is then poured little by little into 4 ounces of diluted nitric acid—1 part strong acid, 1.4 specific gravity, 1 part of water.

THE Testing of Sight.—A report of the Ophthalmological Society of the United Kingdom on sight-testing by spectacle makers, issued by the president, Mr. John Tweedy, dated July 8, states that the Ophthalmological Society, having had its attention called to the fact that the Company of Spectacle Makers proposes to include the subject of sight-testing in the examination for its diploma, and to give certificates of efficiency therein, wishes to express its opinion that, while approving of any measures which tend to increase the efficiency of opticians in their technical work, it considers that such a proposal would be misleading and dangerous to the public to countenance a proposal to certify as competent to advise and prescribe for the correction of vision any one who has not had an efficient medical and surgical training. A diploma such as the Company of Spectacle Makers proposes to grant may lead the public to believe that its possessor is competent to diagnose and treat diseases of the eye, and thus the consequences might follow. Errors of refraction often occur in connection with diseases of the eye. The mere correction of the refraction by means of spectacles would ignore a condition which might do harm, or even leave the life of the patient in danger. Moreover, many errors of refraction can only be accurately measured after the local use of a drug, which should only be employed or prescribed by a medical man, since its indiscriminate use is calculated to aggravate one of the gravest diseases to which the eye is liable. Finally, on general grounds, it is undesirable and dangerous to encourage the public in the belief that affections of any organ of the body can be safely treated by any one unacquainted with its anatomy, physiology, and with the various morbid conditions to which it is liable.

New Materials.

Self-toning Aristo Postcards. Sold by Kodak, Ltd., Clerkenwell Road, London, E.C.

The self-toning Aristo postcards are the latest production of the Kodak Company. They are made, we understand, by the American Aristo Company, whose long experience and success in the matter of Kodion papers is a sufficient guarantee of the excellence of this product. The Aristo self-toning papers give delightful prints, bringing out everything that can be printed from the negative, and for accuracy of results and ease of manipulation are hard to beat. The postcards have the same good qualities, and, being on stiff card, can be used for other purposes than actual postal service if necessary. The colour obtainable on the self-toning Aristo paper and postcards is simple fixing only is a rich and pleasing brown, whilst by treatment in a solution of common salt, a fine purple tone is secured. The results we have obtained with both methods of treatment have been entirely satisfactory. The fine semi-gloss of the surface is particularly adaptable for either broad effects or the rendering of fine detail. The cards are sold in the usual packets, and are not at all expensive.

Crossed Swords Pigment Paper. Sold by Messrs. Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C.

This new introduction in printing papers is a carbon paper for direct printing without transfer, for cold development. The paper for direct sensitising and exposure appears to be lightly coated with pigment, and is similar in appearance to paper prepared for the bath in the bichromate process. It requires to be sensitised in a bath made of one part of a stock solution composed as follows:—

Ammon. bichrome.....	6 grms.....	1½ ozs.
Soda carbonate (cryst.).....	1 gm.....	¼ oz.
in water	100 ccm.....	25 ozs.

and 2 parts of strong methylated spirit.

This diluted solution does not keep, and must be prepared every time it is wanted. The pigment paper is now laid face upwards on a sheet of blotting paper or blotting board. Then in subdued daylight the spirit-diluted solution is brushed over the surface with a flat, soft brush quickly and evenly. It is not necessary to dry the paper in a dark room; simply hang it up by the corners, still attached to the blotting paper, with the film towards the wall. In 5-10 minutes the paper must be dry, and is now at least as sensitive as P.O.P. The paper must be used as soon as possible after sensitising; it becomes useless after forty-eight hours. As the paper gives no visible image, a photometer should be used as a guide to this process. As soon as the paper becomes saturated it must be removed to a dish containing an 8 per cent. solution of acetic acid, at a temperature of deg. R. = 100 deg. Fahr.; sufficient solution must be used to cover the print, and the solution may be used repeatedly. The solution must be allowed to act for one minute. The print is removed and laid on a zinc or glass plate, and laved with a thin sawdust broth, which should not be warmed. This operation is best conducted in a basin or deep dish, which will hold a quantity of the broth, and to which the broth may be ladled by means of a deep ladle or cup. Preparation of this broth, which need not be renewed very often, is made by mixing about 1 oz. of fine sawdust in 30 to 40 oz. of water, to which has been added 30 to 45 grains of Pot. Carb. When directly exposed, the lights will appear at once after the first or second laving; complete development taking place in a very few minutes. Such parts of the picture which require more bringing out could be treated by gentle brushing with a camel-hair pencil. The final operation is to remove any bichromate salts that may remain in the paper. This is accomplished, after rinsing off any adhering sawdust, by placing the prints for half-an-hour in clean water. Then hanging the prints up to dry.

The difficult and many operations entailed by the carbon process has hitherto barred it from use with many amateur photographers, also the effects of the bichromate salts in combination with hot water has often proved a difficulty, but this new paper removes both of these difficulties. The paper, first of all, absorbs no bichromate salts, these are so sparingly applied and so quickly dried, that the sensitising solution is in the pigment surface only; this is immediately removed by the first immersion in cold water, the paper is then dipped in the acetic acid bath and developed in cold water; thus having removed the necessity of single or double transfer, of redeveloping, and of prolonged dabbling in hot water impregnated with bichromate salts. The whole process, sensitising, printing, and developing, can be completed within fifteen minutes, if necessary. It will not enlarge further on these advantages, but can say that in our hands the process has yielded admirable prints, and we have every confidence in saying that the photographer with artistic yearnings and a desire to manipulate his final print so as to obtain a variety of effects has here all that he can desire.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by our correspondents.

NEW ADDRESS OF KODAK, LIMITED.

To the Editors.

Gentlemen,—Owing to the renumbering of Clerkenwell Road by the local authorities, we now find ourselves Nos. 57, 59, and 61, instead of 41 and 43. May we ask you to publish this fact in your valuable journal?—We are, yours faithfully,

KODAK LIMITED.

July 14, 1904.

THE PHOTOGRAPHIC CONVENTION.

To the Editors.

Gentlemen,—There are probably many members who, like myself, were absolutely staggered to hear on Wednesday last week, at Derby, that the P.C.U.K. had amassed a "nest egg" of £450. That a provision for a possible rainy day is commendable everyone will admit, but surely the above sum is quite out of all reason, and it is, I imagine, hardly the aim and purpose of the P.C.U.K. to amass nest eggs in order to hatch out silk umbrellas.

May I also ask why the convention cannot strike out into fresh country and not revisit the old places as has been so often done of late. I gathered from private conversations that many are in accordance with the above views, which are those of

ONE OF THE RANK AND FILE.

A NEW ZEALAND PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Under the heading, "Colonial Photographic Societies," in the B.J. Almanac, you include the Canterbury Philosophical Institute, photographic section. Though the institute flourishes the photographic section has been dead many years. A new society was formed some three or four years ago, of which I send you the programme, giving official designation, officers, etc. Being much away from Christ Church, I have not joined this new society, but I have no doubt you can rely upon the accuracy of the booklet.—Yours faithfully,

CHAS. M. PHILLIPS.

Box 425, Post-Office, Christchurch, New Zealand.

June 7, 1904.

[We are obliged to our correspondent for drawing attention to this matter, and also for sending particulars of the Christchurch Photographic Society, which appears to be a very flourishing concern.—Eds. B.J.P.]

RED SENSITISERS.

To the Editors.

Gentlemen, Some few weeks back Mr. Thorne Baker stated in your pages that he had been quite unsuccessful with Dr. Eder's formula for sensitising plates with Wollschwarz 4B. To those of your readers who are interested in the subject, and who are also members of the Royal Photographic Society, I would point out that Dr. Eder has just presented the Society with a copy of the work, "Beitrag zur Photochemie und Spectralanalyse," in which will be found a very fine photogravure spectrogram taken on a Wollschwarz plate, which shows not only the Fraunhofer lines C, B, a, and A, but even traces of the infra-red Z line, all quite clear, and with a practically even band of deposit from D ½ E to "little a." This work has been in my possession for some time, but I knew it was no use referring to it, unless a copy was generally available, and now this is the case.

In the same paper Mr. Baker gave a formula (April 8, p. 287) containing a 1 per cent. alcoholic solution of Wollschwarz. Being desirous of comparing Dr. Eder's and Mr. Baker's formulæ, both in the spectrogram and practically, I started to follow the latter, but find that I cannot make a 1 per cent. solution of Wollschwarz, there being a considerable residue undissolved.

There is no question about the identity of the dye, but there may be about the alcohol. Perhaps Mr. Baker will tell me whether he used rectified spirit, absolute alcohol, methylated spirit, or what, and also the specific gravity and temperature of solution, so that I can make comparative results, which are required for purely academic and not commercial purposes.—Yours faithfully,
Foots Cray.

E. J. WALL.

A WARNING. To the Editors.

Gentlemen,—I write these lines to put my fellow-photographers on their guard against an individual of respectable appearance who calls on photographers stating that he is a gardener of some well-known gentleman (in my case fictitious, in a neighbouring town) and hands them a written order to photograph a group of twenty—12in. x 10in. (sometimes 15in. x 12in.), at his master's house, and after getting into the photographer's confidence, asks him to advance him some money, as he has run short, which he usually gets, and on going to the house the next day to execute the order, finds it is a fraud. Description.—Dressed in brown jacket, black bowler hat, collar and tie; moustache usually waxed at ends. His right leg is about 4in. shorter than the left (which would easily identify him). The above particulars I have obtained from the police. Fortunately in my case I advanced no money, as I never do so to strangers as a matter of business. He promised next day to call and drive me over, and of course never turned up. He is wanted by the police for several cases in this district. Trusting you will find room to insert the above—Yours truly,
Chippenharn, Wilts.

T. A. TROTMAN.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration or copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- W. Morrison, 22, Bore Street, Lichfield. Photograph of Cat and Mouse, in Chapter House, Lichfield Cathedral.
Miss J. H. Fischer, 18, May Street, Chorlton-on-Medlock, Manchester. Photograph of the Rev. Dr. Carsatelli, seated, in Robes.
Frederick Whaley, Weston Villa, Cheltenham. Photograph of an Enlarged Photograph of six Samoyede Dogs, Hornessed to a Sledge, with Arctic Background Worked in with Black and White Chalks and Dogs Finished off with Black and White Paint.

J. H. FISHER.—“(1) If the circumstances be as stated in your letter we think you have done right in withdrawing the order. (2) If you find your copyright being infringed, at once consult a solicitor well versed in copyright law.

OLD NEGATIVES.—“S. M. H.” writes: “Could you kindly oblige me with the name and address of a firm who accept old negatives?” In reply: We scarcely understand your query. If you want to get rid of the negatives out of your way the local dust-cart will doubtless relieve you of them. If you want a firm to accept them in exchange for new plates there is no one who would do so.

SECONDHAND PHOTOGRAPHIC BOOKS.—W. ANDREWS AND SON say: “We would feel much obliged if you could kindly let us have the names and addresses of firms or private individuals likely

to purchase books on photography.” In reply: We know firms that make a speciality of buying secondhand photographic books. Your best plan, we should think, would be to advertise them in the photographic journals. We do not reply to respondents by post.

TEXODERM.—“PYRO” asks: “Can you inform me the address of a firm from whom I can purchase a kind of celluloid ‘Texoderm?’ It is, I think, an American production, and used for carbon printing.” In reply: We do not know material under that name, but it is probably a form of celluloid. As you say it is of American manufacture, it is possible Messrs. Guiterman, of 35, Aldermanbury, E.C., can supply them; they are the English agents for the American Celluloid Company.

EARLY THREE-COLOUR WORK.—C. HARRAP writes: “As we are at present anxious to determine the exact date of the earliest production in three-colour printing, either British or foreign, may I ask if you can in any way assist us, and at the same time tell us, where such a print can be seen?” In reply: I refer to the Almanac for 1899 (page 682, *et seq.*), you will find some “Bibliographical Notes,” reprinted from “The Journal of the Society of Arts,” and written by Mr. Bolas. These will doubt give you the information you desire.

ARTIFICIAL LIGHT IN STUDIO.—C. GORHAM says: “I had an apparatus made of thin metal sheeting and asbestos, intended to fit incandescent gas lights for our studio, this shape (3ft. 1½ft. deep). The landlady is now having the entire premises installed with electricity. Do you think I could make work with electricity? If so, how many incandescent lamps should I use for very quick exposures?” In reply: A reflector will answer as well with incandescent electric light as it would with gas of equal illuminating power. The greater candle-power of each light the smaller will be the number required. Messrs. Adamson, Charles Street, Hatton Garden, we believe, supply lamps up to two hundred candle-power more.

WASHING BEFORE TONING.—“JODYZER” says: “Some time several paper-makers advised P.O.P. toning as follows:—the prints into toning both without previous washing; and then plunged them direct into the fixing bath.” We find the same makers say:—“On no account must the previous washing be omitted.” We are using a paper where the previous washing is advised and can do nothing with it except by the old method of putting prints direct into toning, and from direct into fixing. Then we find it goes admirably. We asked the people who are supposed to make this paper what happens when not previously washed, and if the fading parties are likely to be increased; they say ‘If you can get results keep to your way, but with regards to the fading properties the question is too complex.’ Can you, please, an opinion on previous washing and no previous washing. In reply: As the makers recommend that the prints should be washed before they are toned, it is pretty clear that failure must be due to your manipulations. It is usual with papers to wash prior to toning, and we ourselves always find that practice. We should say that that treatment conduces to greater stability in the result.

. NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

A Check to the Free Portrait Swindle.

A salutary lesson to the free portrait brethren has just been given at the Chester Assizes, which ought to have the desirable effect of checking to some extent this persistent nuisance. An account of the prosecution appears in our Legal and Commercial Column. The astonishing frequency with which this swindle occurs and thrives, in spite of the repeated warnings in the Press, gives rise to the reflection that there are still many gullible individuals about who are blest with the beautiful idea that much promiscuous philanthropy abounds in England.

The American Fiasco at St. Louis.

A new aspect of the inner workings of American photography is disclosed by the article we reprint in another column from our New York contemporary, "The Photographer." That factions and dissatisfactions exist in American photographic circles we are well aware. It would be strange if it were otherwise. This same state of things obtains in greater or lesser degree in every community in every country. It is a sure sign of vitality. But that internal differences should have so disrupted the great body of American camera workers, in the face of such a big national event as the St. Louis show, to the extent disclosed, will come unkindly to the ears of the admirers of American "hustle." At the same time, our contemporary, whether with full knowledge of the facts or otherwise, pays a tribute to the English photographic section

that will be eagerly seized upon by those more particularly concerned in its achievement.

Ortho Plates.

It has been recognised for some time that the ideal process of orthochromatising plates would be one in which the silver salt alone was dyed and the gelatine quite unstained, thus avoiding the screening effect. Dr. Karl Kieser, of Elberfeld, has now taken out a German patent for effecting this by separating the silver haloids by a centrifugal separator, dyeing them, washing out excess of dye, and then emulsifying. This process would enable one or two useful sensitisers to be used which are now excluded from practical work because the dyes stain the gelatine very deeply, and are not removed in the operations of developing, fixing, and washing.

The Action of Light on Bichromated Gelatine.

Messrs. Lumière and Seyewetz, to whom photographers are under a debt of gratitude for placing on a scientific basis explanations of many obscure photographic phenomena, have increased this weight of obligation by publishing the results of an investigation they have been making upon the composition of gelatine rendered insoluble by the salts of chromium sesquioxide, and the theory of the action of light on gelatine treated with metallic chromates. Briefly, they find that, in the treatment with salts of chromium, the gelatine seems to fix the chromium directly. The acid salt of chromium, though retained strongly by the gelatine, does not seem to have anything to do with the phenomenon of insolubilisation. A constant maximum proportion of the sesquioxide—between 3.2 and 3.5 grammes—is fixed by a certain weight of gelatine, no matter which salt is used for insolubilisation. The dissociation of chromised gelatine by repeated treatment with hot water can be prevented either by washing the chromised gelatine in ammoniacal water under suitable conditions, or by adding to the gelatine, before the chromium salt is introduced, such an amount of ammonia as would in theory saturate the acid of the salt.

Standardising Light Filters.

In 1900 the International Congress of Photography instituted a committee to consider the formation and possible standardisation of coloured screens, and M. Clerc has now presented the report, which is rather interesting, and the suggestions made, if adopted, would lead to considerably more uniformity of results. The reports states, *inter alia*, that M. Monpillard, one of the members of the committee, has proved that the method of coating glass with gelatine

and then staining cannot lead to uniformity, and that however thick the gelatine, the dye had penetrated right through the film, and that therefore varying thickness must give varying intensities. A better method is to add a given quantity of dye to the vehicle and pour a given quantity of the same on a given area. When liquid filters are used, they recommend that the internal cell space should be one centimetre, that the formula for the solution should be expressed in grammes for solids and in cubic centimetres for liquids, and the total bulk should be 1,000 cc. Further, they recommend that when possible the chemical formula of the substance used should be given, and in the case of the organic dyes, the name of the maker and any special marks or numbers of his catalogues describing the dye should also be given. To determine the exact absorptions, when liquid filters are used the absorption of the cell filled with the colourless solvent should be given, and also in the case of dyed gelatine, the absorption of the uncoloured gelatine.

* * *

The Lyceum Theatre.

Our respected opposite neighbour, which for some months has been in process of demolition until little but its façade remains to remind passers-by that a temple of Thespis once stood there, was the scene of a remarkable demonstration just one century ago. To be precise, it was the old Lyceum which stood on the same site in Wellington Street, and which met with the fate of most theatres in the year 1830 by being burnt to the ground, at which the event occurred. Sir Joseph Banks, President of the Royal Society, we are told in the *Times* of July 2, 1804, "went last Thursday evening with a large party of his noble and scientific friends to the Lyceum, to witness the incredible effects of smoke." But this smoke had nothing to do with the conflagration which some years afterwards destroyed the building. As a matter of fact, it was not smoke at all, but coal gas, with which the theatre was experimentally illuminated. "The whole theatre was light with the same, in a novel and pleasing manner; the arch of lights above the stage had a very striking effect, and from the English grate on the stage (which may be fixed in every room) issued a very brilliant and fanciful light." We presume that the scheme included a small gasworks, and that the "English grate" on the stage was the means employed for heating the retort. And this seems certain from what follows: "The products of tar, ammonia, and coke were produced, and much approved of." There is nothing said about the aroma of these interesting bye-products of gas manufacture, but possibly a pungent smell was believed, in the days of tallow "dips" and oil lamps, to be inseparable from any system of illumination.

* * *

Photographs of Paintings.

The physicist and the chemist will tell us that there is no such thing as destruction of matter. It may take upon itself a new form, but, like energy, it is indestructible. But if we turn to the severely practical man, he will say that this is all nonsense, matter can be destroyed and is destroyed, and to prove his point he will probably appeal to statistics which show that the destruction wrought annually by fire in the metropolitan area alone amounts to so many hundreds of thousands of pounds. It is certainly small comfort to the owner of valuable articles like oil paintings by artists of repute, to be told that they have simply been converted by the action of fire to carbonaceous products. "Not lost, but gone—" into the condition of charcoal and gas. Some comfort, however, there would be to owners of paintings, even under such melancholy circumstances, if they had taken the precaution not only

to insure their works of art but also to have them photographed. Every now and then we hear of some disastrous fire, generally at a country mansion far from any effective appliances for dealing with it, in which famous pictures have been burnt to a cinder, and no copy of them remains. The Arundel club, the formation of which we called attention to a few weeks ago, has now been instituted, with sufficient number of subscribing members to enable beginning to be made upon this very necessary work of obtaining a photographic record of old works of art in private collections. Sir Martin Conway is the chairman, and the committee numbers among its members Lord Balcarras, Sir Walter Armstrong, Mr. John S. Sargeant, and other gentlemen well known in the world of art. The committee is now engaged in selecting pictures for reproduction by photography, and we may feel quite sure that in this work they will meet with the cordial co-operation of those who have in their possession pictures of note.

Cameras as Advanced Luggage.

Some two or three years back, when a cabbie had a dispute with the railway companies, he adopted the unjustified expedient of dumping passengers' property on the pavement outside the stations, refusing to take it inside. Ever since the companies retorted in a manner which has cost a cabbie dear. They started the "luggage in advance" system, by which a traveller's personal belongings are collected in London, and delivered at his country address for a fee which would be regarded with disdain by Jellie. The question has now arisen whether a traveller sending a photographic apparatus with his luggage under the new scheme can recover from the railway company in case the articles are lost in transit. The luggage consigned by Mr. F. Smith, a schoolmaster, to the L. and N. Railway Company in April last contained various photographic apparatus (including two cameras), of the value of £17, and the Company contend that they are not bound to make this portion of the lost luggage good, on the ground that in their list of rates for the conveyance of goods by passenger train (published in their time-table) cameras are excepted, and have to be declared and paid for at an increased rate. But the plaintiff declares that such provision does not apply to passengers' luggage in advance, and that no warning of anything of the kind appeared in the document which he accepted when he parted with his property. The Judge of the Holy Trinity County Court, before whom the action was brought for recovery of the value of the property, made the remark that nine out of ten persons now carried cameras with their luggage, and that the point raised was such an important one that he would take time to consider the decision. It is such a common and reasonable proceeding for a traveller to wrap up photographic apparatus with articles of clothing, so as to protect it from damage while travelling, that many will look with interest to the conclusion at which the Judge arrives.

* * *

The Dark-Room Light.

The number of appliances available in the dark-room for altering the quality of the light is surprisingly small in contrast with the variety of forms of apparatus for far less important purposes in photography that can be purchased. We have the well-known incandescent electric bulb within a globe of coloured liquid, but this is comparatively costly; and where a special purpose has to be made the same can be said of the old silicic dipping baths utilised for similar purposes. We have coloured glasses, gelatine-coated glasses, fabrics, papers, and gelatines innumerable, it is true, and possibly

is the cause of the dearth of appliances; but the spirit of true scientific investigation calls for something more. It does not want to be confined to nameless tints that cannot be reproduced from a written description; needs apparatus to render available any variety of chemical solution that can be repeated at will by investigators at the other side of the world as easily as by the experimenter at home; and, as we say, there are few such pieces of apparatus at present available, and still fewer economical. Some little time ago there was described at a meeting of the Quekett Microscopical Society a little contrivance devised for obtaining coloured light for the microscope, but which would be equally useful for dark-room or other lights. The inventor is Mr. J. G. Kingsford, and at the meeting referred to he exhibited several of his tanks in use. Mr. Kingsford (referring to the generally leaky nature of the tanks supplied for such purposes—an objection substantiated by the President's experience) stated that one of his tanks had been in use for over two years without developing any defect. Another at advantage of his vessel was the ease with which it could be cleaned. It consists of two glass discs forming the sides of the tank. A band of metal, thin and flexible, lined with sheet rubber, forms the edge of the tank, and a metal bolt or clip is provided to draw the ends of the band towards each other.

* * *

Sea water seems to have as great a charm for some persons as sea air has for others. We do not mean sea water in the abstract, but as a necessary part of scenic display more especially connected to holiday folk, but as a specific preparation of salt water. Some have held that a glass or two of this compound is an excellent appetiser for breakfast, possibly because of its undoubted nastiness, for many hold that medicinal remedies are useless unless they provoke a feeling of nausea in the swallowing. At this time of year some surprising amateur is sure to start the notion of using sea water for photographic purposes, and he writes to the editors either to say that he has used it with advantage, or to ask whether it can be used with impunity. Most certainly it can. If the distressed inquirer happened to be picked, and one of the few survivors in a small boat which for days had been the sport of the cruel waves, with no water, water everywhere and not a drop to drink," he would be compelled to develop his photographs and even mix his developer and fixing bath with ocean. We can assure him that developing photographs *cum grano salis* would not lead to any great disaster. But unless he is thus *in articulo mortis*, as one might say, he would certainly do better to use fresh water. The amount of soluble salts in a gallon of sea water is not great, and there is nothing in them which will come into serious conflict with the chemicals employed in developing, fixing, washing plates or films. But we should advise those who from circumstances beyond their own control are obliged to use sea water to give their photographic plates, at a final rinse in fresh. Bathers in the sea are aware, less their skins be of an unusually insensitive kind, of a slight stickiness which clings to the hands and face after a morning dip, and some are never quite comfortable until they have had an opportunity of access to fresh water. We may assume that the delicate gelatine surface of a plate film must suffer the same experience, although it cannot express its feelings in the same way. Sea salt is hygroscopic, and we can imagine that when tiny particles of it are left entangled in the gelatine we have the nucleus of disintegration. For moisture in any shape must be kept from gelatine if we want to preserve it, and a final rinse, or, better still, soaking in fresh water is obviously

the remedy for possible difficulties with plates brought about by the enforced employment of that which is salt.

The New Cyanines in Lippmann Emulsions.

Dr. Neuhaus, whose name is so well known for his researches in connection with the Lippmann process, has been testing ethyl-red, orthochrome, and pinachrome in emulsions for this process, and he gives some spectrograms which show that not only is the old sensitiser of cyanine + erythrosine + glycin-red superior as regards red sensitiveness, but that it gives far more even deposit—that is, there are no recognisable minima of sensitiveness, as is the case with the three other dyes. The mixture sensitises close up to the C line, whilst pinachrome, the most satisfactory of the other dyes, only sensitises up to about D $\frac{1}{2}$ C. Neuhaus emphasises the importance of not being misled by spectrograms, and points out that although there is apparent even density, the blue and violet regions appear before the others, and that actually the emulsion is about three times more sensitive to the more refrangible rays, and that in camera work a yellow filter is necessary. The addition of glycin-red to ethyl-red, orthochrome, and pinachrome emulsions improves the sensitiveness to yellowish green and greenish blue, without increasing that to red. The following passage is worth careful attention:—"If a plate sensitised with cyanine, erythrosine, and glycin-red, and exposed to the prismatic spectrum, be developed, the deposit of silver from the red to the violet appears absolutely equal. From this the conclusion must be drawn that the plate possesses equal sensitiveness for all colours. We have seen above that this conclusion is false, for the plate has at least three times too great a blue and violet sensitiveness. The prismatic spectrogram thus gives rise to a fallacious conclusion of the worst kind. Would that these facts were more generally appreciated! The expert can naturally make a correct deduction of the colour sensitiveness of the plate from the results obtained with the prismatic spectrum. When, however, as happens every day, spectrograms of this kind are published in journals destined for lay readers, there is again caused in wide circles quite false conclusions over the actual sensitiveness of the plates. To the plate makers this may be agreeable, but 'the man in the street' has no advantage from it."

—————

THE Occurrence of Radium with Uranium.—A little time back Mr. B. B. Boltwood published in the "Chemical News" a preliminary notice of an investigation of the ratio of uranium to radium in various minerals. The Hon. R. J. Strutt has for some time been engaged in a similar investigation, which, though the results are not yet matured, seems to be leading to the conclusion that this ratio is constant, as in Mr. Boltwood's experiments. An interesting case is the mineral torbernite, or copper uranite. This mineral forms transparent green tetragonal crystals the composition of which is accurately represented by the formula $\text{CuO} \cdot 2\text{UO}_3 \cdot \text{P}_2\text{O}_5 \cdot 8\text{H}_2\text{O}$. The substance dissolves easily in sulphuric acid, forming a perfectly clear green solution. This solution, when boiled, gives the radium emanation, and the quantity of emanation produced in one day is about the same as that yielded by the same weight of Joachimsthal pitchblende. The percentage of uranium is also about the same. If the radium in this mineral has been produced since the formation of the mineral (and the recent quantitative experiments of Sir W. Ramsay and Mr. Soddy on the absolute rate of production of the emanation seem to make that certain), there is practically no choice as to what the parent substance should be. Uranium is the only candidate. The great complexity of most of the radio-active minerals may make it difficult to obtain conclusive evidence by studying them. But here there seems to be no alternative but to conclude that uranium is the parent.

PHOTOGRAPHY AS A PROFESSION AT HOME AND ABROAD.

On more than one occasion of late we have referred to the present state of the photographic business in this country, and the poor future there seems to be before it, both for employees and employers. Our object has been to advise all those who contemplated entering it as a business or profession—whichever it may be called—to give the matter their serious consideration before coming to a decision on the point. The present state of the business, especially as regards portraiture, is at a very low ebb, with but little prospect of immediate improvement.

In our issue of the 8th instant we directed special attention to the present state of the labour market in England. In Germany it seems that a very similar state of things obtain as here. On reference to page 585 ante it will be seen, from a return made by Stores' Studios, reprinted from the "Photographische Chronik," that the wages paid to assistants range from 25s. to 300s. and 350s. a month; but the number that receive the latter sums is limited to one each. The average wage, it appears, is about 110s. a month. Out of the numbers quoted sixty-two earn more than that sum, and eighty-two less. The hours worked are mostly long, ranging from 8 to 11, but only six worked the shorter time.

In the United States things seem to be very similar. On page 591 ante will be found an article by Mr. Dundas Todd, Editor of the "Photo Beacon," who has devoted a great amount of time in investigating this subject. In it he says that before a recent convention "I made the statement that I believed that at least 75 per cent. of the fraternity, whether employer or employee, did not have an annual income exceeding \$500, and urged my hearers to contradict me if I was wrong; but it was admitted unanimously that my figures were correct." Now, \$500 in America are equivalent to £100 in England, and we should say that at the present time, in this country, fully 75 per cent. of photographers—employers and employees—are not making even so much as a hundred a year net profit out of their profession.

On former occasions we have mentioned that our advertisement columns, "Situations Vacant" and "Situations Wanted" are a pretty fair indication of the existing state of the labour market. But the columns devoted to "Businesses and Premises" are also a good indication of the state of business by showing the number of businesses there are for disposal and the stated returns they make. Of course, there are many reasons why businesses come into the market, but we venture to say that in the majority of cases whatever other reasons may be given, the profits made are not in accordance with the ideas of their owners, hence the disposal.

It is interesting to note the returns that are mentioned in some of the advertisements, and we may well surmise that, as quoted, they are not understated. We will quote from one or two advertisements that have recently appeared: "Takings £5 weekly," "Takings £4 weekly," "Returns £250," etc. Now, when one considers that out of these sums rent and, probably, taxes have to be paid; material—plates, paper, mounts, as well as enlargements and finishing, have also to be reckoned as out-goings; also an assistant of some sort is necessary; the profits on such businesses must be reduced to a very small figure. Another point in connection with these small businesses is that, generally, the prices charged for the work are exceedingly low, and must, necessarily, leave but a small margin of profit.

There are many businesses in the suburbs of London, in small country towns, that we venture to say do bring their owners anything like the income mentioned by Mr. Dundas Todd, namely, a hundred a year, all expenses are paid.

The so-called "coupon system" has done a great deal of harm to those in a small way of business, at least in London and its suburbs. Here three cabinet portraits are taken for half-a-crown, and the sitter is supplied with four "coupons." If he, or she, disposes of three of them to friends, he or she gets another three portraits free of commission. This means that there are negatives to take, retouch, and prints to make and mount for ten shillings. Of course, if a large business is doing these lines it can be made to pay. But if only five or six sitters a day are taken, what can the net profit amount to per year? It is true that something is, at times, obtained by way of extras, but this does not amount to much at all. When all these matters are taken into consideration there is little to wonder at that there are so many small businesses in the market.

Let us for a moment consider what has brought about the state of things about, for photography was at one time a very lucrative business and it still is with a comparatively few who have a wealthy clientèle and do the high class of work. It is the simplification of processes and the methods of working. Plates, papers of various kinds are now sold ready for use, and there is very little knowledge required to use them, and that is quickly acquired so as to produce a clear, clean photograph which, we sorry to say, satisfies a considerable portion of the public. It follows as a matter of course that any business in which there is very little to learn is sure to be quickly drenched with mediocre practitioners in every country. Bankruptcy reports that have from time to time appeared in our columns often show that the bankrupt statesman or business knowing very little about it at the time, frequently with borrowed capital. Some employees, owing to the difficulty of obtaining engagements and the salaries offered, have been induced to commence business in a small way on their own account, with the aid of friends, thinking that if they could only clear journeymen's wages they would be better off. Alas for some of them and their friends. In the above, and previous articles, we have pointed out to those who imagine otherwise, that photography, either for employees or those who contemplate starting in the business, is not by any means so lucrative as they suppose. The same conditions, we find, prevail also in Germany and America, and probably in all parts of the world, that is not at all surprising, for the reasons mentioned.

THE Sun's Luminous Clouds.—When the sun's surface is examined or photographed with a good telescope it is seen to possess a most intricate structure, which has been compared to the appearance of snow upon a grey cloth. The bright spots which give this impression are luminous clouds floating in a solar atmosphere, just as the clouds of the earth are suspended in the air. The light we receive from the sun comes from the luminous clouds, which cover an area of about one-fifth of the surface. When relatively cool vapours collect in depression in any part of this surface, dark sun-spots are produced, and when parts are elevated above the general level their brightness is increased, and they appear as patches of a greater brilliancy on the mottled surface. These lucid patches can often be seen of the sun with an ordinary telescope, but investigations of recent years have shown that what is thus visible is but a small part of what actually exists. For several years Professor G. E. Hale, Director of the Yerkes Observatory, Chicago, has been perfecting a method of photographing this flocculent material, most of which is invisible any time when the sun is shining.

PHOTOGRAPHIC TAXIDERMY.

ACCORDING to the dictionary definition, taxidermy is "the art of arranging, preparing, and preserving the skins of animals, so as to represent their natural appearance," and it does without saying that a successful taxidermist must be an artist. But the modern method of setting up what used to be called "a stuffed animal" is very different to that which obtained a few years since, and as we shall presently see, photography is lending potent aid in the work. That the art of taxidermy has advanced of recent years by leaps and bounds must be evident to any one who has paid a visit to the Mammalian Galleries or the Bird Gallery of the Natural History Museum at South Kensington. And more especially is this the case with any one who is old enough to remember the terrible specimens of stuffed animals which have been exhibited at the British Museum in Bloomsbury. Animals with visible stitches along the whole length of the abdomen, with a tuft of straw sticking out here and there to emphasise the fact that they were really stuffed, and not alive. In a recent number of the *Scientific American* a number of photographs are reproduced which illustrate the method of building up an animal form, to be clothed with a natural skin, as now practised at the American Museum of Natural History. First of all, a rough framework is constructed which agrees in its measurements with those taken of the animal to be represented immediately after it was shot. To this framework are attached in their proper places the skull, legs, shoulder blades, and pelvis of the animal, and it is strong enough to support the weight of the modelling clay, which is now attached to represent the muscles. The workman, it need hardly be said, is not a common mechanic, but a sculptor, and he works mainly from photographs. These pictures have been taken, wherever possible, from life at the Zoological Gardens and elsewhere, the animals having been narrowly watched by an expert photographer and snapshotted whenever a good pose presented itself. With wonderful patience the clay is applied to the framework with frequent reference to the original measurements and the photographs, while occasionally the skin, which has been carefully prepared and partially tanned, is stretched over the growing form by way of trial. At last the clay image is completed, and then a plaster mould is made from it. From this mould the complete animal is subsequently cast, the clay model and the bones being entirely discarded, iron rods supporting the legs and body. Nothing of the original animal remains but the skin, and this fits the finished structure like a glove. Of course, there are some minor finishing touches to be given with colour to the margins of the eyes and other parts, and it should be mentioned that the hoofs, nostrils, etc., are conveniently made in papier maché. It is evident that the mould once made, the rest of the work, except the finishing touches, is more or less of a mechanical nature. The finished animal can be made of any light plastic substance, of which there are many to choose from. The main point of interest to our readers is that camera pictures furnish the copies to work from, and huntsmen of big game are so often photographers that they will be able to work with a view to the after preparation of any rare specimen which may fall to their lot.

The Sheffield Photo Company accomplished a smart piece of work in Liverpool recently. Three cinematograph cameras, two of which were operated by Mr. Mottershaw's sons, were taken over in view of a visit of their Majesties the King and Queen, and 1,500 feet of film were exposed from favourable situations. The pictures were once developed, and part of them were exhibited the same evening in Liverpool.

KÖNIG'S COLOUR FILTERS.

DR. KÖNIG, whose name is so well known in connection with the new cyanines as sensitisers, has suggested the following as suitable filters for three-colour negatives for printing from:—

Stock Solution for Blue Screen.

Violet crystals	4 g.
Acetic acid	5-6 drops.
Hot water	100 cc.

Stock Solution for Green Screen.

Flavazine T.	3 g.
Patent blue	6 g.
Green I.	9 g.
Hot water	330 ccm.

Or—

Flavazine T.	2.5 g.
Patent blue	6 g.
Naphthol green	4 g.

Stock Solution for Red Screen.

Red I.	5 g.
Warm water	200 cc.

The actual screens are made as follows:—

Blue Screen.

Stock dye solution	6 cc.
Gelatine solution, 8 per cent.	100 cc.

Green Screen.

Stock dye solution	5 cc.
Gelatine solution, 8 per cent.	100 cc.

Red Screen.

Stock dye solution	4 cc.
Gelatine solution, 8 per cent.	100 cc.

Of these coloured gelatines 7 cc. should be poured on to every 100 sq. c. With these screens the relative times and exposure with a plate sensitised with orthochrome is respectively 1, 3, 6; with pinachrome plates, 1, 4, 3. M. Monpillard has determined the exact absorptions of these screens, and states them to be as follows:—Blue screen transmits from $\lambda 410$ to $\lambda 460$, or from "little h" to $F \frac{2}{3} G$, the first green screen transmits from $\lambda 500$ to $\lambda 550$ or $b \frac{1}{2} F$ to $D \frac{1}{2} E$, and a band in the extreme red from $\lambda 700$ to $\lambda 730$, which is the region of "little a"; the green screen containing naphthol green passes the same band on the green, but absorbs the red band. The red screen only passes from $\lambda 590$ to $\lambda 680$ or from D to B. It is obvious from the above that certain portions of the spectrum are entirely missing, namely from A to B, which would in the ordinary way have no effect on a plate, then from D to $D \frac{1}{2} E$, and from $b \frac{1}{2} F$ to $F \frac{2}{3} G$, and also the violet beyond "little h."

THE French motorists who have taken part in the De Dion tour through the southern counties of England during last Saturday's run from Oxford to London, through Windsor and Henley, included an inspection of Windsor Castle, for which the King had given special permission. Every member of the party was an ardent photographer. The use of the camera was sternly forbidden within the castle, but dozens of snapshots were taken from the Terrace, and the Dutch Gardens were photographed from every possible point of view. Private O'Brien, of the Coldstream Guards, who was on sentry duty on the Terrace, was turned out of his box, and the prettiest French lady of the party was installed in his place. O'Brien, with shouldered rifle, was stationed in front of his fair prisoner, and half a dozen cameras snapped the picture. Private O'Brien, who was obviously nervous, begged for a copy of the photograph, and a Parisian lady doctor took his name and company and promised to send him one.

ELEMENTARY THREE COLOUR WORK.

I.

To the would-be student of three-colour work, unless he decides to take some particular text book, such as Klein's Translation of Hübl's classic work, the various scattered papers on the subject are extremely confusing, and if he follows each writer the result must be a most hopeless muddle.

In the first place, a spectroscope is always considered to be an absolutely essential part of the outfit, and it certainly is for the theoretical student, but for the practical worker, he who wishes to obtain results with the least expenditure of time and trouble, it is not only quite unnecessary but a delusion and a snare. In the first place he, as a rule, cannot correctly interpret his results, and the results can be quite misleading. It is far better for him to at once purchase Hübl's book and use the charts given with it, and adjust the light filters by the aid of them alone.

It is necessary in the first place to decide whether liquid or dry filters are to be used. The one and only convenience of liquid filters is that the actual composition and consequent absorption is fixed, when working to a given formula, and that it is extremely easy to adjust a filter by the addition of dye or water. The disadvantages are first that to be of any use they must be optically worked and are then extremely costly, secondly, one has to use the same cell for all three filters, which entails taking to pieces and cleaning in between the exposures, and thirdly, there is no proof that the solutions used will keep.

To elaborate the first point is hardly necessary, as anyone may refer to a price list of optically-worked cells to find out their cost. The second point is that the same filter-cell must be used for all three exposures; this is important, because the cell walls may differ in thickness, or the cell itself in internal diameter, though only slightly. It is a point strongly insisted upon by Hübl, and one which, if I may be allowed to speak from personal experience, may easily lead to troubles, not necessarily in absorptions, but in noncoincidences and image points. To assume for one moment that it is possible to use (3) separate cells and keep them filled with solutions and obtain constant results, is to carry assumption too far. Dr. Eder has carefully measured the absorption of a methyl-violet liquid filter after some weeks' preservation and proved most conclusively that the spectrum absorption alters most markedly, and be it noted that this was kept in the dark and is merely a single dye solution. Tartrazine, as I have already pointed out, in solution, by comparatively short exposure, loses some of its yellow constituent ray and becomes more green, and, when some years ago, using Hübl's acid green and picric acid filter; I found that the mixed solution would not keep three days in the dark, without becoming perceptibly paler, more yellowish, and this without any perceptible precipitate. In fact it was not till totally erroneous results in colour rendering was obtained that the fact was noted.

Most of the filters recommended for three colour work are solutions of one or more organic dyes and these are extremely sensitive in some cases to external influences, such as the chemical action of glass, if one may call external the action of the interior of a bottle. For more than 12 years now one of the ready tests of the hardness of glass has been to keep a solution of eosine in it and measure the difference in colour due to the action of the salts dissolved from the glass, light in this case playing no part. Possibly this may be the reason why when stock solutions of aniline dyes are kept for some considerable time, although prepared with distilled water and kept in the dark and carefully filtered, one frequently finds a flocculence or distinct change of colour.

Dry filters I think are preferable, but they are a little trouble to make, and the majority of the directions given in articles and text-books are to me simply anathema maranatha

and evidence of careless haphazard working. Let us take for instance, the normal instructions for preparing such dyes which usually run after this fashion: "patent plate glass coated with a 50 per cent. solution of Nelson's No. 1 gelatin at about 95 deg. F., and placed on a levelling slab to set, then dried. Fixed out lantern plates, washed and dried to answer the purpose." Now I would point out that following these directions one may obtain a film of gelatine of about .003 or .1 of an inch, and if these two films are soaked in dye solutions the absorptions are totally different.

Whilst it may be convenient to coat up, in fact it is more convenient to coat up a number of screens, there is no reason so far as I can see, why a definite amount of gelatine and dye should not be apportioned to a given area of glass, and König's instructions are in this respect a model to other writers, for he gives dye solutions of definite strengths, a given amount of the same and gelatine per unit area of glass so that one can easily calculate out the necessary quantities for any sized filter.

Lumière's directions differ from this in that a given quantity of gelatine is recommended, a given strength of dye solution and a given time and temperature of soaking, so that the result is practically the same, because given one kind of gelatine one strength of dye, and a fixed temperature, the absorption is constant.

If a liquid filter is given, there is no difficulty in calculating out the necessary quantities of dyes for a dry filter, and if it is kept constant the amount of gelatine may be practically varied without any noticeable alteration of the absorption. As an example, I may give the following three filters, which were calculated from the liquid filters used in a cell of 1 inch internal width, and proved to be correct. The liquid filters were:

RED.			
Bisberich scarlet	1:500		
GREEN.			
Picric acid	1:5000	45 parts	
Acid green	1:5000	55	,,
VIOLET.			
Pyoktannin	1:5000		

The cubical contents of cell were measured and the result was to make a dry filter of corresponding absorption, every square inch of glass had to contain or be covered with gelatin containing 0.001 grammes of pyoktannin; 0.0725 g. picric acid by 0.18125 g. of acid green and 0.035 of Bisberich scarlet respectively. Obviously then with such directions the amount of gelatine and water are immaterial.

It will be noted in conjunction with above that merely the names of the dyes are given. This is not sufficient, the maker's name must also be given, and further, the plates for which the screens are adjusted, those above being thus more clearly defined, Bisberich scarlet being made by Kalle and Co. Bisberich, and acid green and pyoktannin by the Berlin Actiengesellschaft für Anilin fabrikation, and the plates Lumière panchromatic.

There is another important point in connection with filters, which the theoretical student must decide for himself, and that is what absorptions he is going to work to. Rough speaking, filters may be divided into three classes:

(a) Those that divide the spectrum into three zones, namely from red to D, from D to about F, and from F to the violet that is to say, three spectral zones without overlap or lacunae or vacancies.

(b) Those that divide the spectrum in three zones, each zone overlapping its neighbour, and

(c) Those that divide the spectrum into three zones with lacunae or gaps in between.

As to which is correct and which is wrong I am not going to enter at any length, but will point out that Dr. Miethe

those trichrome prints are the finest I have ever seen, adopts the "a" system; he is supported by Eder, and also Howard Farmer, and Gay Symmons. Newton and Bull adopt the "b" system, as does also Hübl. Whilst the third or "c" system, that adopted by Carbutt and König. Mr. Newton and Bull's paper on trichromatic filters (B.J., May 13, 1904) should be referred to for further extension of this division. Personally I believe that all three systems will give satisfactory results, and that more depends upon the exposure than has hitherto been pointed out, because in practical trichromatic work, we do not get pure spectrum colours, and with varying exposures the three systems run one into the other, because, take for instance, a yellow pigment, and it reflects not only yellow but red and green spectrum rays as well, and so on with every other colour. In fact it is an invariable law that any coloured pigment reflects that on each side of its chief spectrum colour.

Having said so much, I may as well add that these notes are again but the "idle thoughts from an idle hour" and by no means intended to be absolute, but they are at least the outcome of many years experimental work whether right or wrong.

E. J. WALL, F.R.P.S.

SOME QUALIFICATIONS OF A SUCCESSFUL PHOTOGRAPHER.

The following paper, delivered by Mr. A. A. Bish, of Chippewa Falls, Wis., before the Eighth Annual Convention of the Photographers' Association of Wisconsin, and reprinted in "The St. Louis and Canadian Photographer," contains a fund of advice and suggestion which, if followed by professional photographers, will do much to raise the standard of the profession. It also affords a clue to the methods of the American knights of the camera in the advancement of individual professional photography worthy of the attention of English photographers. Some of the qualifications of the successful photographer, as a subject of much importance to the profession, and one in which much of interest might be said. That some men succeed in photography and others do not, as is the case in all their lines of human endeavour, is to be expected; but to be able to prove absolutely just why one man can succeed when another in the same field of usefulness fails dismally is not an easy task.

"For the past ten years those of us who have been attending the conventions have heard much about the art side of photography—have heard it from those who are authorities on this subject. Not only have we listened with profit to the artists with brush and pencil, but to those who are equally artistic (in their field) with that magic tool, the camera. To-day the results of this education on the mass of photographers, as shown by the high class of work now done as compared to that produced even in the early nineties of the past century, is simply wonderful. We were not then so well aware of our many weaknesses as we are to-day, but no doubt the awakening came at an opportune time, and that period might even now be most appropriately called the 'dark ages' of photography. Yet we are as yet only well started toward the light of a brighter and a better day.

We have heard much about the picture-making side of photography (and it was sorely needed), yet it has been only within the past year or so that much has been said, either in the platform or through the columns of our professional magazines, on the subjects pertaining to the business side of the photographic profession.

I will not attempt to define a successful photographer, but will, rather, endeavour to call attention to some of the things that, in my judgment, go far toward making a man successful, whether he be engaged in this business in the city or in the country towns; but more especially may these remarks apply

to the worker in the smaller cities, as it is here that he comes into closer communion, as it were, with his fellowmen and with his customer.

Now, in order to discuss this matter, I propose to classify my few remarks under the following heads, namely: (1) Honesty, (2) Health, (3) Ability, (4) Industry, (5) Knowledge of the Business.

The first subject that claims our attention is "Honesty." I am sorry that there is so much that might be said on this theme. This virtue alone, if carefully practised in all our business and social relations, would do much to firmly establish the profession on the high plane where it rightfully belongs. I hold in my hand a business letter to a gentleman in my town from the proprietor of what, a few years ago, was, perhaps, one of the best known studios in the Middle West. I will now read this letter that you may better understand my point:

C——, I——, September 3, 1903.

Mr. S—— J——,

Chippewa Falls, Wis.

Dear Sir,—Yours of September 3, with cheque enclosed, at hand. Thanks.

We have never sent a portrait without a frame, and it is not safe—it would surely spoil the picture. Why not have one of our gold-leaf frames we wrote you about? Think either one would be beautiful. The patterns of the frames are of the latest designs. We can make up a frame for 18 dols., a little narrower than the one we wrote about.

Would not advise you to get a cheap frame, as the portrait is beautiful, and you would surely spoil it. Awaiting your early reply, we remain,

Yours truly,

I. SOAKEM ART CO.

Now, the portrait referred to in this letter was a sepia enlargement, finished and mounted on 16 by 20 cardboard, just as we all get them by mail or express from those who make a business of this class of work. The gentleman who brought me this letter is a customer of mine, a well-posted and well-to-do business man. He had placed the order for the portrait with this firm on my advice, as they had the original negative, he having only a small sepia platinum print from the same. He paid them 35 dols. for this portrait, which was the price they had made him, but, as he expressed it, he did not propose to be held up for an 18-dols. frame. I did not appear on the surface in this deal until he brought me this letter, inquiring of me if it were true that a picture of this character could not be sent safely unframed. I answered the letter myself, on my own business letter-head, and, I guess, rather pointedly, too, for the portrait came by return express, and, needless to say, it did not surely spoil it to send it without a frame, thus proving, in the mind of his customer, that this firm were either badly mistaken on the important point of shipment of their wares or else they were guilty of using unscrupulous and dishonest business methods. I dare say that the latter conclusion was the one arrived at in this case, and the firm has thereby lost a possible future customer, and the profession at large has at the same time been lowered just so much in his estimation. A man in any business who descends to methods, very properly called schemes and fakes, need not be surprised if he himself is classed with fakirs. The calibre of the man engaged in any business is what gives it standing. You may be an artist in your chosen line, but the profession to which you aspire is given credit or discredit in proportion to the way its individual members grace or disgrace it. The frame scheme, if it had come from some fake house, would have been different. Fakirs we will have with us perhaps, but let the gulf between us and their skin games be so wide that we cannot for one moment be classed with them.

Not only in these things, but in our work we are not honest with ourselves, or our patrons as well, unless we at all times do our very best, and even then strive to do better. It is not what we have within our grasp, but what we can see above and beyond us, and what we try for, that really helps us. Money is not the only thing we work for, and unquestionable business methods will drive more business away than all the ad. writers in the world can get and hold for you.

Now let us carefully examine ourselves on this most vital question and see if we are honest in our daily conduct of business, honest in our endeavour to better serve our patrons by taking advantage of every opportunity to improve, not being content to rest on the glory of past achievements, or to entertain for a single moment the arrogant impression that we have reached the acme of artistic or technical excellence, which is only a sure sign of rapid and complete decay.

In the matter of 'Health' I need not remind you of the great blessing that we enjoy in the possession of a sound body, and having this, we should guard it most carefully. In these modern times, with their attendant rush and bustle, the business man has much to try strength. Talents, either natural or acquired, cannot presume to take a high flight nor hold a steady course when housed in a diseased or pain-racked body. True, the photographer of to-day has been able to dispense with many obnoxious chemicals and not a little of the tedious and confining work which fell to the lot of the worker of other days, such as the preparation of his plates or paper, yet there is enough left of both to work havoc unless much care is exercised. Observance of careful habits and plenty of out-door exercise do much to assist nature in keeping healthy.

To those who are so inclined, a day or two taken occasionally from the daily grind, with rod or gun, is recommended, and I notice that those who combine out-door work along with that of the studio enjoy, as a rule, better health than those who do not do so, and from experience and observation I heartily endorse combining the two. A bright eye, a quick step and a cheerful manner indicate good health, and, possessing these, you are much better able to animate your sitter and assist in securing that indescribable 'something' individuality, which is the perfume of the flower of portraiture.

So, aside from the added enjoyment we are able to get out of life, we owe it to ourselves to keep our bodies healthy, that we may better attain our full measure of usefulness.

I will now pass to the third topic, that of "Ability." By this I mean a fitness to perform a given work. Business ability counts for much. First, last, and all the time the photographer should study business methods as well as the technique of his profession. To be sure the business end should not lead us near that dangerous rocky roof 'money madness,' yet it must be understood to be the motive-power in the studio which turns the wheels of progress.

Happy is the man who can combine the two in a clever way that neither the artistic on one hand nor the business end on the other seem to suffer. One thing especially I mention here, and that is, always carry out the promises that you make, even if you have to sit up nights in order to do so. We must be square-toed also in all our transactions, at the same time have it understood that you give full value for all money paid over your counter under all circumstances. One thing certain, our guns are all right, but very much depends upon the men behind the guns. *We must be men!* Men who have a capacity for independent action, not those burdened with moral stupidity, nor an infirmity of will that prevents one from 'catching hold and lifting.' Men who will not act for themselves will not count for much when the benefit of their effort is for all.

Next, perhaps, to his ability as a business man and a photographer nothing has so much to do toward making him success-

ful or otherwise, as does the manner in which he introduces his product to the public.

A few weeks ago I sat in the showroom of one of the best studios on the Pacific coast, talking to the educated and awake proprietor, when a lady stepped from the elevator passed into the office. The saleslady was busy, it was late, and she came to the room in which we sat and asked the proprietor if he could show Mrs. A. her proofs. He excused himself, and, stepping into the office, I heard him accost her pleasantly, not fawningly, mind you, after we from my position in the show-room, I saw him indicate her a chair near a window; he, seating himself opposite, began unrolling the proofs in question and sat discussing with her in a quiet, business-like way. I could not help but think how differently those proofs might have been shown her across a desk, without comment and without courtesy.

In the practice of medicine it is said that the person is almost as valuable to a man as scientific knowledge, and can all, no doubt, now recall to mind some good doctor of experience in whose presence you never failed to notice a quiet, dignified, yet forceful individuality which seemed to render him so different from other men. This quality may be acquired, to a greater or less extent, by us all, and, by cultivation, may be made to shed its beneficent rays on all with whom we come in contact.

But, returning to business methods more properly, it seems to me that it would be better if we photographers would regard ourselves as business men, and not pose so much as artists only. We need not lose sight of the artistic excellence to which we must all aspire, but let us do business in a business-like way, and be of some economic value in the community in which we live.

I am informed that less than one-third of the photographers of this section—and this is no worse than other parts of the country—seem to have an account at the bank and to do business through the banks. This state of affairs cannot be true in other trade or professions. No manufacturer or merchant would think of doing business otherwise. I am informed that it seems to be growing better slowly. No one would hope that everyone who has not tried this will hasten to do so immediately on his return home. Have your books, make it a business to deposit daily, or weekly, at least, your receipts, against which you can check all bills, which should always try to discount. This alone is quite an improvement and will amount to more during the year than you imagine. Then you come in contact with people who do business correctly, and you will unconsciously acquire better business methods yourself. Then keep a simple set of books, keep track of receipts, expenditures, and stock. If you do all this you will have less time to criticise the way our politicians run the Government or the equally-stirring subject of our times.

'Industry.' Without industry a man cannot succeed in photography any more than he can in some other vocation. Unless you have a capacity for hard work of the most painstaking kind you had better keep out of the ranks, if already in the business, the sooner you get out the better for all concerned. Honest labour degrades no one, but, on the contrary, it ennobles and enriches all. So much to do, yet it is surprising how much you can accomplish if you keep pegging away. However, we must work intelligently, and we need not make tread-mills of our studio work. In other words, we must like the work and put our whole souls into it. The captains of to-day in the industrial world are not men who have tinkered with this and with that, nor have they frittered away their precious time on fads and fancies, having set their eyes on the mark aimed at, they have sweated neither to the left nor to the right until the goal is reached.

Seest thou a man diligent in his calling; he shall surely prosper.

In conclusion, I wish to impress upon the minds of all that in order to enjoy a full measure of success in photography it is essential that one have a good broad knowledge of the subject, which comes through a liberal education. The principles of pure photography may be easily mastered, but when you have learned to focus a camera and develop a more or less printable image on a modern dry plate, it does not follow that you are a photographic artist any more than the young medical student is a doctor as he emerges, diploma in hand, from the class-room. Indeed, not as much, for, as a recent writer has said, the student of medicine or law has spent, and with good reason, much valuable time and not a little treasure in preparation in fitting himself to begin the practice of his profession, while, unfortunately, just the reverse is true of our work, or, at least, such has been the case in the past. We value a thing largely by what it has cost us in time and money; therefore, if a man or woman enter the broad field of labour armed with little or no training along either business or artistic lines, he or she cannot be expected to add weight or dignity to a vocation the past achievements or the future possibilities of which they are practically ignorant.

The American mechanic and specialist knows not only the technique of his profession, but its history as well and its relations to other trades and professions. He is up-to-date always, for he reads his trade magazines and journals, thus keeping in touch with his brother workers; he is energetic, wide-awake and progressive; he has a keen appreciation of success and its attendant joys as well as a more philosophic view of adversity. Now, if this be true in other trades and professions in our country it should also be true of photography, for, as in music, painting and other kindred arts, photography appeals to the higher and better nature of man.

A few educated men with some art training and a love for the work have done more in the past few years toward securing a recognition of the merits of photography than all the combined plodding of forty years of photographers. The day of the all-round man is past. We are now in the age of specialists. As yet, perhaps, only a few have had the courage to break away from the beaten path, but the result of their success, where known, will only be the means of bringing more and more to the breach, and what will be the result, you ask. It will be this. Each man in his chosen line will develop to the highest point his branch of the work, while his co-worker will do likewise in his. The public appreciation will follow even more rapidly than it now does, and as the call for still better work increases, as the public state is educated, the remuneration will increase as well as the demand. Then the unprincipled and dishonest man, the man with little or no ability, the lazy man, or the one with little pride in his work or in his profession, will fall farther and farther in the rear, while the intelligent, earnest disciple of the great Daguerre will succeed to the field which is now almost deserted by the portrait painters."

On Reading Advertisements.—The "Druggists' Circular" for July makes some pertinent remarks about the usefulness of the chemist and druggist in business reading advertisements. The writer asserts that, in addition to good reading, the advertisement pages of a pharmaceutical journal really form a most important part of the current literature of the chemist in business, and should be read as promptly and conscientiously as the other pages of the journal. He points out that the chemist who reads advertisements learns much about various things connected with his business which he may not have immediate use for, but which makes his reserve stock of information of greater value to him. We can fully endorse the pronouncements of our contemporary. Their application to the photographic dealer also is equally clear.

DEVELOPERS WITH ACETONE.

It is some time now since the attention of photographers was directed towards acetone as a substitute for the alkaline component of a developer. One or two formulæ for such developers have been spread abroad, notably that of MM. Lumière and Seyewety, but in almost every case they have been pyro-acetone formulæ, and pyrogallol seems to have been the only developer to which much success with acetone has been ascribed.

According to Eder's *Jahrbuch* for 1903, C. W. Cyapek experimented previously to Lumière with acetone, and partially replaced the potash in a metol-hydroquinone developer with it. But experiments seem to indicate that acetone can successfully replace the entire proportion of alkali, not only with pyrogallol acid, but with many other developers as well. Moreover, certain modifications of the pyro-acetone developers already published give such excellent results in our hands, that it has seemed worth while devoting some small space to an account of their behaviour.

A foreword regarding the exact behaviour of acetone is first

of all desirable, as the discussion between Drs. Eichengrün, Eder, and Lüppo-Cramer respecting Messrs. Lumière's explanation of the behaviour of this compound was sufficient to arouse considerable interest in Continental circles during the last two years. The question, to which there has been more than one answer, is whether acetone and an organic developing agent will work alone, as a developer, or whether the presence of sodium sulphite is also necessary? It has been contended that acetone bisulphite with hydroquinone will make a workable developer also, on the one hand, whilst against this has been brought forward the argument that the acetone bisulphite must have contained some sodium sulphite as an impurity. Certain it is, however, that acetone, hydroquinone, and sodium sulphite give a good developer, only our experiments pointed to a larger proportion of acetone being necessary with hydroquinone than with pyrogallol to ensure efficient working.

The accompanying diagram illustrates the difference between the character of gradation obtained with two H. and D. strips, one developed for eight minutes with ferrous oxalate (A), the other for three minutes with pyro-acetone.

Pyro-acetone gives a negative with abundant half-tone, good even gradation, and a plentiful supply of density, and should be very serviceable for portraiture, and also good for landscape work where sufficient exposure has been given.

The two following "stock" solutions will be found serviceable for portraiture: A. Pyrogallol, 1.5 gm., of 15 grs.; sodium sulphite, 10gm., or 100grs.; sulphuric acid, .5cc., or 5 drops; water 200 cc., or 4 oz. B. Acetone; ordinary pure acetone. In some cases a larger quantity of sulphite is recommended. Thus Vogel, in his *Taschenbuch der Praktischen Photographie* (1903), recommends twenty parts of sodium sulphite to 1.4 part of pyrogallol. Take for use, twelve parts of A and one part of B.

It might here be noted that in preparing the A solution the sulphite and acid should be added to the water before the pyrogallol, as if the sulphite and pyro be alone added, the sulphate which occurs generally as an impurity in the former oxidises some pyro, and causes the solution to have a pink colouration, which a normal amount of sulphurous acid does not remove.

Development with pyro-acetone is fairly rapid, and should be continued until the image is through at the back of the negative, and it seems thoroughly dense on examination by transmitted light. Great care must be exercised between development and fixing. If the plate be put straight into the fixing bath, the film will become marked with large spots or streaks. Owing to the greasy nature of the acetone, the negative must be held under a running tap for some moments before immersion in the hypo; the film is thus rid of acetone and its by-products with the developer, and fixing takes place readily.

If hydroquinone is to be used, about the same proportions as with pyrogallol may be taken. Thus, 1.5 part of hydroquinone, 10 of sulphite, and 200 of water suffice for A, whilst to every ten parts of this about one and a half of acetone must be employed.

Pyro-acetone works exceptionally cleanly, and bromide is not necessary except in cases of over-exposure. For this reason it is very suitable for panchromatic plates, and deserves special recommendation in this respect.

T. THORNE BAKER, F.C.S.

X-RAYING the Earth.—For five years two mining and electrical engineers and inventors, Messrs. Daft and Williams, an American and an Englishman, have been experimenting in British Columbia, in Alaska, in Siberia, and in the United Kingdom, with devices for discovering, by electrical means, deposits of metals that were undiscoverable by ordinary mining methods. In principle as in results the invention is most simple, though many electrical difficulties had to be overcome in perfecting it. A current of electricity conveying a series of taps or ticks like an ordinary Morse message, is put into the earth by means of special transmitters. This current makes its way through the earth over a larger or smaller area, yards or miles, as the operator may choose—but to what depth none can say—from one electrode to another. Then, with a telephone receiver and a steel spike, two operators walk over the charged areas, and, sticking the spike into the earth anywhere, pick up the current, and the mysterious ticking tells what is hidden in the earth as plainly as though one saw with an X-ray eye. Away up on the rocky steep slopes of the barren hills that frown down on Coniston Lake and Windermere there was seen a fortnight ago the result of a remarkable challenge, and the establishment beyond question of this new scientific discovery, as fascinating in its exposition as it is apparently destined to be valuable and revolutionary in its application. Half a dozen sceptical mining experts and as many non-scientific ordinary folk, who did not know a copper lode from a load of hay, climbed precariously over the barren heights with a telephone receiver in one hand and a steel spike in the other, prodding the earth, listening to nature telling over the telephone in language the simplest could understand of the existence and the exactest location of her stores of wealth, hidden hundreds of feet below in the heart of the rocky hillside. Then the rocks were dynamited, and the lode exposed to show that nature was telling telephonic truth.

THE FAILURE OF AMERICAN PHOTOGRAPHY AT THE ST. LOUIS EXPOSITION.

[From "The Photographer," New York.]

There are no photographs in the Fine Arts Building at the St. Louis Exposition.

According to Professor Halsey C. Ives, Chief of the Department of Art, there will be none. In spite of the United efforts of the photographic Press, in spite of the expectations of the pictorial workers in photography the world over, what, was proclaimed a photographic triumph one year ago turned out to be a bubble, the existence of which was seemingly dependent upon the whims of three men. These three men, with a nonchalance born of unlimited power in their respective positions, blew the bubble from one to the other until it burst.

The visitor in search of evidences of photographic endeavour at the world's largest exposition is directed to the Liberal Arts Building. If he be English, satisfaction will be his; and if American, sorrow.

Along one side of the immense building, housing anything from stuffed Polar bears to French millinery, is ranged a row of miserably lighted stalls, filled with a heterogeneous mass of photographs, ill spaced, and incoherently hung. The only means by which the identity of the display can be established is through several beggled placards, attached to some of the pictures, in which the names of several well-known professional photographers, evidently looking for all the advertising the law allows, stare at you from an immeasurable distance. There is no catalogue.

If the visitor approach the row of stalls from one end he is immediately impressed with the fact that photography at St. Louis consists of Paris panel portraits of more or less prominent St. Louis citizens. There are countless numbers of them. An attendant, one of the very few, volunteers the information that the rows of substantial citizenship had something to do with the exposition. This, then, is a reward handed to the citizenship in lieu of dividends! The fact is also disclosed that this acreage of Paris panels was not passed upon by the jury. Heaven forbid!

Further along the line there are evidences of the fact that a few of the big men were big enough to surmount obstacles or else, ignorant of passing events, were thoughtless enough to send a few pictures, and those not of the best.

In all about three hundred prints adorn the stalls. A free view of some of them is obstructed by various interesting and profitable additions. In front of one of the stalls a gentleman of persuasive mien adjures you to have a penny made into an interesting souvenir of the fair; at another, a woman gifted with a saintly expression and remarkable avoirdupois squirts Florida water at the passer-by, meanwhile proclaiming the fact that attar of roses can be had at a remarkably low price.

Germany, France, and Italy are all represented by a small, well-chosen collection of pictures. England, as usual, is thorough, and all other displays fade into absolute insignificance in comparison. Splendidly hung, well selected, and carefully catalogued, England's 242 prints bear eloquent witness to the fact that, whatever the internal strife may be, when necessity comes there is unity of purpose and determination to win. No vainglorious zealot here to say "What care we for national loyalty or the future of our art?" The mountebanks are hustled to the rear, and solidity, modesty, and reserve come to the fore. This is a world show, and England must maintain her position amongst the nations.

Upon whom shall we fix the responsibility of this miserable fiasco? Colonel A. J. Ockerson, Chief of the Department of Liberal Arts? Professor H. C. Ives, Chief of the Department of Art? or Alfred Stieglitz, Director of the Photo Secession?

Upon Colonel Ockerson, who promised?

Upon Professor Ives, who refused? or

Upon Alfred Stieglitz, who dictated?

But judge not, gentle reader, until you have heard what all three have to say. "The Photographer" has stated its position with absolute clearness and presents facts without bias and without comment other than is warranted by the situation as having a bearing on the future of photography.

Here is what Colonel Ockerson had to say to "The Photographer" in reply to numerous questions:—

"As far as I am concerned, the question of photography at the fair remains where it was several months ago. The photographers

assured that if there was room in the Fine Arts building photographs would be exhibited. It appears that there is no room, hence there will be no photographs in the Fine Arts building.

I do not wish to recount ancient history, but to make my position perfectly clear to the photographic public I feel some matters should be considered which entered into the matter of the photographic exhibition at St. Louis. In the first place, I am deeply interested in every branch of art displayed under the supervision of the department, and especially so in the photographic section. I assured early in the history of the fair that it would be a hard task to reconcile the photographic workers and bring them together amicably. This inspired me to spend considerable effort in the direction of convincing the photographic people that it was to their best interest to make the exhibition of photographs at the fair the most successful in years. I attended the meeting of the Photographers' Association of America, held in Buffalo in 1902, talked with the members of the association, and gained their support. I had correspondence with many of the leaders in photography, and endeavored to get at some method of harmonising all of the contending interests; and, while I could take no official notice of such a condition in the photographic ranks, did all I could towards bringing to light what seemed to be a lamentable condition of affairs.

I asked for suggestions from many sources, including the members of the Photo-Secession, the Photographers' Association of America, all of the leading camera clubs, and many of the leading photographers. As a result of the replies to these requests for suggestions I formulated a plan by which seven representatives of leading organisations in America were to act as a jury of opinion.

The invitations forwarded to the seven organisations selected representatives, the statement was made that the pictures were to be hung in the Liberal Arts building. This immediately started a crusade on the part of the ultra-artistic photographers looking for the installation of a photographic exhibit in the Fine Arts building. I took the matter up with Professor Ives, and he assured me that if there was room in his building he would gladly call a jury to consider the pictures submitted by the photographers, and would hang such as passed. This information was in due course submitted to the photographic public in a special announcement issued by my department.

Out of seven organisations invited to participate in the selection of pictures by sending a representative to serve on the jury of selection two responded. The two were the Photographers' Association of America and the Chicago Society of Amateur Photographers. The other five declined on one pretext or another. At this time I had a correspondence with Mr. Alfred Stieglitz, leader of the Photo-Secession. The sum and substance of the correspondence, which covered a period of several months, was in effect the statement on the part of Mr. Stieglitz that the members of the Photo-Secession would not exhibit their prints unless they were assured that at least one of the number sent would be hung without consideration of price. To this I replied that the rules of the department forbade such action, and that even such large corporations as the United States Steel Company had to submit their exhibits to the Exposition and they were accepted. Various arguments were advanced by Mr. Stieglitz, all of which I answered, reiterating my original statement.

The upshot of the matter was that Mr. Stieglitz, acting for the Photo-Secession, declined to exhibit, and the matter was dropped. In failing to gain the support of the seven organisations originally invited to send representatives, I appointed a committee of three men prominent in photography to act as a jury, and the pictures were then passed upon by these gentlemen.

I am disappointed at the showing made by the American photographers at the fair. The Exposition has spent several thousands of dollars in preparing for this particular exhibit, and the result has not repaid the effort. Very few photographers responded, and all those that did not send their best work. What should have been the representative exhibition of photography ever held in America is now a commonplace show at best.

It is not for me to name the cause of this unfortunate condition of affairs, but I feel a deep interest in the cause of American photography, and I hope that the day is not far distant when all of the workers in pictorial photography can find a common meeting-place, and at the value of the particular work each is engaged in, and, such another opportunity is given them, unite with shoulders to the wheel, and place American work and American workers to the front where they belong."

THE PREPARATION OF WATER DEVELOPMENT PLATINUM PAPERS.

PRINTS upon paper where platinum forms the main body of the image are obtained in several ways. The original plan was to develop the image upon, or more correctly by, immersion in a hot solution of neutral potassium oxalate. Beautiful prints were obtained by this method, but the use of a solution at 180 deg. F. proved to be a great drawback to its general adoption. The introduction of cold development for the production of prints in platinum in 1892 proved a great step in advance.

The subject to be dealt with here is the preparation of platinum paper that requires no special developing solution, the only requirement after printing the image being to submit the print to moisture, or to immerse it in water for complete development, or it may be held in the steam issuing from a tea-kettle, or placed in a damp box for several hours, at the end of which time development will be complete. The easiest and quickest process is to simply dip the print into plain water, when the development can be easily watched and stopped at the right moment. One of the principal and most important salts used in the preparation of any kind of platinum paper is ferric oxalate. Although this salt can be purchased very cheaply, it may be advisable in some instances to prepare it. This can be done with ease and certainty in the following way: Take one pound of chemically pure perchloride of iron (sometimes called sesquichloride of iron), place it in a two-gallon clean stoneware crock, pour upon it a gallon and a half of boiling water, stir with a strip of glass until dissolved, then pour into this hot mixture (stirring well at the same time) one pound of stronger water ammonia. The stirring must be done rapidly: The solution will quickly begin to thicken, and will closely resemble coffee grounds. Just as soon as the mixture thickens heavily the addition of ammonia should be stopped and the crock stood aside for the precipitate to settle. This precipitate is nothing more or less than pure iron rust, known chemically as hydrated peroxide of iron. As soon as the precipitate has settled well the clear liquid must be decanted off. This clear liquid is a solution of ammonium chloride. Fill the crock again with clean cold water, stir the contents well, and allow to settle again. When settled, decant once more.

Continue this operation until the washing is complete, which may be ascertained by adding a few drops of nitrate of silver solution to a small quantity of the clear decanted liquid. As soon as no opalescent effect is produced the precipitate of pure oxide of iron is ready for use. It must now be poured into a large glass funnel, with a strong filter-paper inserted, or, better still, use two filter-papers, with a small tuft of absorbent cotton pulled out like a cobweb, placed at the apex of the filter paper. When fitted into the funnel this cotton will prevent the paper from splitting at the point of greatest pressure. About ten ounces of distilled water should be added after the first filtering is completed, so as to wash out the ordinary water. The washing being now complete, dissolve half a pound of c.p. oxalic acid in one pint of boiling distilled water in a stoneware crock, take out the oxide of iron from the funnel with a glass strip, and place it into the hot solution of oxalic acid. Continue this until the whole of the contents of the funnel has been transferred to the crock. Stir well. If the oxalic acid has not all dissolved, it will not matter, because there will be a considerable quantity of water held by the oxide of iron, which will be more than enough to dissolve any excess of acid. When this mixing takes place it should be done under no stronger light than a gas jet or an oil lamp, because the salt which is forming, namely, the ferric oxalate, is extremely sensitive to light. In fact, the whole of the operation in preparing this salt of iron, from the time the oxide and oxalic acid are brought together must be conducted away from any actinic light.

The mixture must be stirred two or three times a day for about four days, when it will be found that nearly the whole of the oxide has been dissolved. The liquid that is left will be found upon decanting to be of a brownish-green colour, and when tested by the hydrometer will indicate 60 or 70 on the scale; this means 60 or 70 grains of pure ferric oxalate to the ounce of liquid. This is the ferric salt that is required for the preparation of the paper. It must be fully understood that the operations from this time on must be carried out under a yellow light. Ferric oxalate solution will be found to

clear better by settlement than by filtering. It must not be evaporated down to a solid, because the excess of heat for this operation would injure the salt and produce ferrous oxalate. It is this body that must be avoided if it is desired to produce a perfectly coated paper. The ferric oxalate being ready, proceed as follows:—

Procure the necessary number of sheets of paper to be coated (suitable paper can be obtained from any large photographic stock dealer). It must be plain paper, not salted. Sheets about 18 by 22 inches can be bought ready for use; sizing of the paper previous to coating is not necessary. Now make up the following stock solutions, using distilled water only: Gum arabic, white, 1 ounce; dissolved in hot water, 3 ounces; chloroplatinite of potassium, $\frac{1}{2}$ ounce; water, 6 ounces; oxalic acid, chemically pure, saturated solution; oxalate of potash, saturated solution; lactic acid, 4 ounces; potassium chlorate, 60 grains; hot water, 5 ounces; nitrate of lead, 240 grains; hot water, 4 ounces; ferric chlorate (chlorate of iron), $2\frac{1}{2}$ ounces.

Ferric chlorate for use in the preparation of this paper is made up as follows: Take two ounces of ferric oxalate solution and add thereto 4 drams by measure of the potassium chlorate solution above given. All the bottles used for this work must be amber-coloured glass, except for the gum arabic, so as to insure safety from action of light.

A drying box or closet will be required, a small cupboard in a room will answer, or a moderate size packing case may be used. If a cupboard is to be utilised several lengths of copper wire must be stretched from side to side, attached to screw-eyes, the same kind as used for picture frames. Allow space enough for the bottom of the sheets of paper to hang about eighteen inches above the top of a small gas stove placed upon the floor, beneath which a sheet of tinfoil has been placed for safety. Upon the top of the gas stove place another piece of clean tinfoil about a foot square. This is to distribute the heat. The products of combustion will not affect the paper, if it is not to be kept too long before use, say for a month. If a packing case is to be used, then a few one-inch holes must be bored in the top to allow the air to circulate and take the moisture from the paper.

A small gas stove must be used in the same manner as described for the cupboard, of course, allowing sufficient space between the heated sheet of tin and the bottom of the sheets of paper, so that they do not become scorched. Having the drying closet ready and a few dozen wooden photographic clips at hand, proceed as follows: Procure an amber-coloured glass tray, say, 8 x 10 inches, and cut the paper into strips 9 inches or $9\frac{1}{2}$ inches wide. Cut some strips of thick cardboard half an inch wide and 9 inches long, or strips of glass will answer better. Two dozen of these will be required for twelve strips of paper. The paper must be examined, and a mark made upon the back with a lead pencil so as to indicate the right side to coat. Now place a glass strip at one end of the paper upon the back, and clip it with three wooden clips, one at each end and one in the centre, reverse the paper and attach another glass strip in the same manner to the other end. Continue this until the twelve pieces of paper are complete and lying on top of each other ready for coating. The sensitising solution is to be made up in the following manner: Ferric oxalate solution (fluid measure), 4 ounces; ferric chlorate, 3 drams; chloroplatinite of potassium solution, 3 ounces; nitrate of lead solution, 3 drams; potassium oxalate solution, 4 drams; oxalic acid solution, 2 drams; lactic acid, 10 drops; gum arabic solution, 1 dram.

These may be mixed in an ordinary amber-coloured wine bottle, corked with a clean cork, and shaken up well, then filtered through absorbent cotton placed lightly in the neck of a glass funnel into a sixteen-ounce wide-mouth amber glass bottle. This is the sensitising solution. Pour this into the glass tray, take one of the clipped sheets of paper, holding the ends with each hand, bend the paper into shape like the letter U, bring one end down upon the surface of the liquid, then, by gently raising one hand and lowering the other, the paper will glide smoothly upon the surface of the sensitising solution and become coated as perfectly as if coated by a machine. Repeat this operation two or three times, hold up the sheet of paper cornerwise so that any excess of liquid may drain into the tray, and allow one corner of the paper to touch the inner edge of the tray. The paper must now be suspended in the heated closet to dry. Coat the other sheets of paper in the same manner. When all are dried they must be removed and laid aside, away from light, for a short

time to cool. They must then be coated again upon the same and suspended to dry in the reverse position; this is to equalise the coating. A sheet or two of blotting paper may be placed at the bottom of the closet to absorb any liquid that may drop, and of blotting paper may be clipped at the bottom of the sheets to prevent the liquid from falling.

As soon as the second coating is dry remove the clips, trim the ends by cutting off that part held by the clips. The paper is now ready for use. Any sensitising solution that may be laid aside and can be added to some fresh solution within a week; if not, it must be thrown into the waste can for saving platinum waste.

Having a suitable negative ready, cut the paper to the required size, say a 5 x 7 view, place it in the printing frame, and if possible to sunlight. Print the image well in. When removed from the printing frame and immerse immediately in a bath of warm water. Almost instantly the image will develop with intensity. It must now be placed in a clearing bath of muriatic acid, 1 part to water 50 parts. In a short time the image will be cleared and a rich warm black print upon a white ground will be the result. Two or three such clearing solutions should be used to insure complete elimination of the iron salts. The print should now be washed and dried, ready for trimming and mounting.

The paper that may be left over may be packed in an amber tin case, such as is used for platinum paper, with a thorough coating of chloride of calcium wrapped in several folds of clean paper, and either sealed or tied with string.

It will be found that this paper will print much better after being kept a short time. Should the paper become at all damp it will become well printed out when exposed in the printing frame. In the process of drying the paper do not use galvanised iron gas stove, or spots upon the coated paper will result from the specks of zinc carried off by the heat.

Paper for giving brilliant prints from weak or thin negatives made by this process by adding double the quantity of ferric chlorate to the sensitising solution and printing in very deeply.

To ascertain the best quality of paper for use it would be well to plan to test a few pieces before coating the larger sizes. Ordinary plain photographic papers may always be depended upon to produce reliable and satisfactory results. Papers that have a slightly rough surface produce the best results.

In preparing paper for water development it must be clear that any and every kind of paper cannot be used. Some papers contain a considerable quantity of kaolin and other matters, while others contain the residues of the chemical used in the bleaching process. All these bodies interfere with the action of the platinum contained in the sensitiser. Such papers, baryta where employed as a coating upon any kind of paper, prevent perfect deposition of platinum. The deposited platinum is extremely small in quantity, consequently the image is poor in quality, the colour being at all times a bluish or bluish grey.

The organic properties of the paper itself have much to do with the chemical action which causes the deposit of platinum.

Other salts can be used in combination with ferric oxalate as sensitiser for water-developed platinum paper, such as sodium oxalate and ammonium ferric oxalate, but in either case the image has a very weak appearance upon development, particularly the last-named salt, which will produce upon some papers a greenish appearance. It must also be understood that whatever the drying closet may be used it will be necessary to provide an inlet for the air. Also to take every precaution for the prevention of dust entering the drying closet.

The process of double coating may be facilitated by hanging sheets of paper after the first coating and drying in a moderate box or closet, the bottom of which has a sheet or two of paper wetted with warm water, the coated sheets of paper hanging upon stretched wires, the same as in the drying closet. Fifteen or twenty minutes in this closet will allow the paper to absorb just enough moisture to permit of its being bent and handled with freedom. It is not intended to make the paper damp, but to allow it to absorb enough moisture to make it pliable. This means the second coating may be effected with ease and without allowing the sensitiser to flow over the back of the paper.

The addition of the gum solution to the sensitiser en-

ing to be accomplished without previous sizing of the paper. The extra sizing of the paper has caused many failures in preparing paper for one's own use, rendering the paper more absorbent than if it had not been sized. This may appear strange, but it is nevertheless a fact. The paper should be passed through a calendering machine after sizing, to close the pores and thus give a suitable surface that is practically non-absorbent, no matter whether the surface is smooth or rough. These remarks have been made to prevent disappointment and to aid in producing a perfect paper without going into a course of experiments. This small percentage of gum enables paper to be used such as Whatman's. The only point to be attended to when Whatman's paper is to be sensitised is to reduce the quantity of ferric chloride solution to a fourth of that used in the formula given, otherwise the paper will give prints possessing great contrasts. The printing upon Whatman's paper will require double or treble the time that would be required for printing upon smooth paper. The process of clearing or fixing must also be continued longer than with smooth paper. If this is not attended to a considerable portion of the ferric salt will remain in the paper, and will soon cause a very decided yellowing of the white parts of the picture.

If muriatic acid is not on hand a solution of oxalic acid may be used, one ounce of oxalic acid to thirty ounces of water, using three separate baths. Should oxalic acid be used the hands must be washed in lime water to obviate risk of oxalate poisoning. A solution of muriatic acid (hydrochloric acid) is the best clearing agent for pictures made upon the paper described for water development.

A. J. JARMAN (Wilson's Photographic Magazine).

FORTHCOMING EXHIBITIONS.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Exhibition. Secretary, Edward Kitto, The Observatory, Falmouth.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-ninth Exhibition, New Gallery, Regent Street, London. Secretary, W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. M. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. sec., H. C. Lamingway, Tooker Road, Rotherham.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

November, 1904.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, C. B. Appleby, Barnbygate House, Newark.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Cotton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sergeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, J. Lawton, 20, Clarence Square, Gosport.

December 5-7.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Park, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Patent News.

The following application for patents was made between July 4 and July 9, 1904:—

Colour Photography.—No. 15,204. "Improvements in apparatus for colour photography." William Norman Lascelles Davidson.

The following applications for Patents were made between July 11th and July 16th, 1904:—

Printing Frames.—No. 15,421. "Improvements in artificial light photographic printing frames." Benjamin James Hall.

Exposure Meters.—No. 15,498. "Improvements in photographic exposure meters and in the means of calculating depth of focus." R. and J. Beck, Ltd.

Apparatus.—No. 15,587. "A contrivance by which photography may be carried on without using an ordinary dark room." Archibald Whitehead.

Printing Frame.—No. 15,600. "Printing frame for photographic post-cards." James Thomas Milne.

Plate Holder.—No. 15,739. "Improvements in photographic plate or like holder." William Lawrence Parkinson.

FROM Messrs. A. E. Staley and Co., of 19, Thavies Inn, London, E.C., we have received two interesting little booklets which may be had for the asking. One is entitled "Flashlight Photography without Apparatus," and deals intelligently with the use of the various flashlight candles and powders made by Dr. G. Krebs, of Offenbach, now sold only by Messrs. Staley under the name of Geka Preparations. The other is a well illustrated and admirably got up catalogue of the well-known Premo Cameras.

New Apparatus, &c.

The "Merito" combined Developing Plate Holder and Plate Dryer. Sold by W. L. Parkinson, Limited, 62, Dale Street, Liverpool.

This simple piece of apparatus is strongly made of black celluloid, and its utility and advantages are manifest at once. It is intended

to hold the plate during development and fixing, etc., and so avoid soiling the fingers, while later it can be employed to hold the negative in an upright position to dry. Being made of celluloid, it is easily

cleaned and not liable to contaminate or rust. As an accessory for developing, whereby the negative can be examined without risk of scratching or marking the film, it will appeal at once to the amateur. It is very cheap, and should have a good sale.

Bayer's Premier Combination Gold Salts. Made by the Bayer Manufacturing Co., 20, Booth Street, Manchester.

This preparation forms an excellent combined tone-fix bath, which is specially recommended for professionals. It appears to be very rich in gold, and therefore yields a pure gold tone on nearly every brand of P.O.P. It dissolves readily, and, owing to its mode of manufacture, yields immediately on solution a fully mature bath, ready for use. The temperature of the bath recommended when toning the prints should be 60 to 70 degrees F. In order to avoid spots, it is advisable to place the prints in the bath one by one, and keep them in constant motion until toned. A thorough washing completes the process. A bath of 20 oz. is sufficient to tone about 35-45 half-plate prints (6½ by 4½) or 80-100 quarter-plate (4½ by 3½). When the solution becomes weak, it can be strengthened by adding an equal quantity of fresh solution to the old bath.

The "Primus" Nature Postcards. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

This series of postcards has many novel features, one of the best being that whilst the side upon which the print is mounted is one of a charming series of shades of art paper, the reverse side is of the ordinary white card. Some of the cards are printed with a series of chaste ornamental embossed designs in bold coloured inks, and a motto is also added, of which there are twelve selected from the poets; so that in many cases additional interest is added to the picture by this description. Others again have only an embossed

design, but all are in excellent taste. The packets contain an assortment, and are sold at popular prices.

V.B. Postcards. Sold by Albert E. Mallardain, 51, Cheapside, London, E.C.

These postcards are prepared in the same way as the well-known V.B. self-toning printing-out papers. They are faintly printed daylight and are fully developed in plain cold water. The application of a weak solution of hypo (about ½ oz. to the pint) for thirty seconds fixes them, and a final wash completes the process. The prints produced are of a fine Vandyke brown colour, and the simplicity with which they are produced, owing to the briefness of the exposure and the simplicity of the after processes, should secure a large sale for them. They are put up in convenient packets of ten, and are inexpensive.

New Books.

Photographische Bibliothek. Vol. 19. Die Farben-photographie. Dr. E. Koenig. Gustav Schmidt, Berlin.

This small volume is intended as a guide to three-colour work those who are interested in photography. The aim of Dr. Koenig has been to examine and explain, in a clear and succinct manner, theory and practice of the art, so far as it may depend upon action of light directly. Mechanical printing processes are there beyond the scope of the publication, which rather deals with colour photography in those forms that lie within reach of the amateur. Koenig's treatment of the subject is exceptionally lucid, and instructions are quite up to date.

Photographische Bibliothek. Vol. 20. Die Herstellung von Diapositiven. By P. Hanneke. Gustav Schmidt, Berlin.

This book on the preparation of positive photographs for lantern projection, or window decoration, will be a welcome addition to the library of many photographers. Herr Paul Hanneke, the editor of the "Photographische Mitteilungen," has the subject at his fingertips, and, as might be expected under such circumstances, we have here a very complete set of formulæ brought within a small compass which every admirer of the lantern slide will find useful. If we offer a suggestion for future editions, it is that more attention should be given to the collodio-bromide emulsion processes. They are of most beautiful, and, we think, the inclusion of reliable formulæ for the making of these emulsions would add considerably to the value of the book. It is true Herr Hanneke gives the name of one well-known maker of collodio-bromide emulsion, but to work with such material deprives the photographer of half the enjoyment attached to the process, besides the opportunity of exercising much skill.

"Photography on Tour." 132 pp., price 1s. Published by Dawkins and Ward, Limited, 6, Farringdon Avenue, London, E.C.

This little volume, being thoughtfully built on pocketable lines, likely to become a constant and reliable companion to the photographer who travels much, especially abroad. It contains sound advice and reminders on many things that the said photographer would probably overlook until the occasion arose, when it would be late, and touches in a practical way the numerous difficulties and dangers which beset the photographic tourist. The proper preparation and packing of apparatus; precautions in carrying and changing films and plates; photography on a cycle, on horseback, and shipboard—these are some of the subjects discussed in one section. In others, contributors deal with the treatment of special subjects such as animals, skies and clouds, yachts, heavy seas, architectural, alpine and other mountain scenery, flowers, street scenes, statues and monuments. For the benefit of the Continental tourist is a brief vocabulary (for use at a dealer's) in French, German, and Italian, also a letter in these languages requesting permission to photograph. Exposure is not omitted from the volume, but is presented in a manner calculated to appeal to the photographic novice, and as generally helpful little compendium of photographic information ready to be found elsewhere in one place, it promises to fill that curious void known as "a long-felt want."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Inst.	Name of Society.	Subject.
.....	Nelson Photographic Society....	Reading. Mr. Ambrose Smith.
.....	Rotherham Photo. Society	<i>Odds and Ends.</i> Mr. J. Leadbeter.
.....	North Middlesex Photo. Soc.	Lantern Slide and Print Competitions.
.....	Hull Photographic Society	General Meeting.
.....	Watford Photographic Society	Informal Meeting.

Commercial & Legal Intelligence

LYNDHAM AND Co., Limited (Photographers, Acton).—Issue on 29 of £500 second debentures, part of a series created May 8, to secure £3,000, charged on the Company's undertaking and property, including uncalled capital. Holders—E. P. Martin, J. L. Radford, Cedar House, Hillingdon; and B. J. Taylor, Avenue Road, Acton. No trustees. Total amount previously issued of same series, £2,500.

ROBERT'S STORES, Limited, Bournemouth.—At the board meeting on the 16th inst., Mr. James I. May, Mr. William F. Thick, Mr. Thomas A. Twitchett were elected on the directorate of the Company. These gentlemen have been connected with the business in the capacity of managers of departments since the formation of the Company. It is anticipated that their election as directors greatly strengthen the board and promote the interests of the Company, the photographic department of which, we understand, is in a flourishing condition.

JUDD AND MANNERS, Limited.—Capital, £500 in £1 shares. Objects:—To acquire the business carried on by A. Manners at 76, Dean Street, E.C., as "Judd and Manners," and to carry on the business of wholesale and retail chemists, druggists, dyers, salters, oil colourmen, importers and manufacturers of, and dealers in, pharmaceutical and other preparations and compounds, makers of, and dealers in, proprietary articles, electrical, chemical, photographic, optical, and scientific apparatus, and materials, etc. No initial capital issue. A. Manners is first general manager and secretary.

On the last night of Henley Regatta, a man broke into the business premises of the Maidenhead Photographic Company, Station Road, and stole about £3 in money and some photographic apparatus, a cheque-book, a paying-in book, and other articles. He had carelessly packed up a box of camera lenses and prints, but, apparently having been disturbed, left it behind. He committed a good deal of damage on the premises. The man was afterwards arrested by London detectives with some of the stolen property in his possession, on Monday morning the Maidenhead magistrates committed him for trial. Detectives John Course and Charles Keys, L Division, saw accused enter the Hero of Waterloo and the Olive Branch public-houses in Waterloo Road on Saturday night, and, as he carried a suspicious looking parcel, he was watched, and finally arrested on suspicion. Prisoner gave the name of Henry Jarvis, 177, Whitechapel Road, London.

A PAINFUL case was heard on Monday by the Dewsbury Borough Magistrate, defendant being a young woman of attractive appearance, named Maud Lathom, late cashier for Mr. A. F. Gothard, photographer, Dewsbury, who was charged with embezzling £2 10s. on 22nd of March last. She had been in his employ for some years, the most implicit confidence was placed in her; but from circumstances brought to his knowledge he felt bound to question her; she owned that she had taken about £40, and that she promised to repay if he would forgive her. He promised to do so, but soon afterwards felt compelled to go into the matter again, and it was discovered that she had formed an intimacy with a man named

Whitehouse, and that this fellow had had from her a considerable amount in sums varying from 5s. to £2, and that the defalcations came to over £100. Though that was the case—and it was a painful discovery to make about a trusted servant—Mr. Gothard still asked the Bench to deal leniently with the girl, for the sake of her future. Only one case, that of embezzling £2 10s., paid to her on her master's account by Mrs. Wilson, of the Little Saddle Inn, for photographs, was taken, and to it the accused pleaded guilty. She said, in answer to questions, that she had repaid £1 3s., that she had no prospect of further employment, and that her parents were too poor to take her in; a sister, she believed, would do so. The magistrates said they had taken into consideration Mr. Gothard's wishes, and in the hope that this would be a warning to the prisoner and lead her to take another course of life, they would only bind her over in £10 for six months. This was done, and she was then set at liberty.

A FRAUDULENT Edinburgh Photographic Canvasser.—At the Edinburgh Sheriff Court on Monday, Thomas Menzies Bell appeared in answer to a series of charges of theft by fraud. In all twenty-two charges were preferred against Bell. Of these, nineteen were to the effect that between July 1, 1903, and April 30, 1904, he represented to different persons residing in Edinburgh, Heriot, Stow, Ormiston, Pentcaitland, Gladsmuir, and Melrose that he was canvassing for orders for the portrait of Jas. Swan, cattle salesman, Edinburgh, and that for payment of 21s. he would deliver to each of them a framed portrait, thus inducing these persons to give him £19 19s., which he appropriated to his own use. The other three charges were of a similar nature, the frauds being committed between April 25 and May 25 of this year, in Edinburgh and Roxburgh, when he said he was canvassing for orders for the portrait of another cattle salesman named Andrew Oliver. Bell pleaded guilty to the charges, and an agent stated on his behalf that he followed the calling of a photographic canvasser. Unfortunately, in the case at issue he had failed to deliver the photographs, but he actually had these at home ready for delivery. He had had a good deal of domestic trouble lately, his wife having died not very long ago, after a protracted illness. The fiscal pointed out that these frauds commenced in 1903, and that in point of fact, none of the parties, with one or two exceptions, had received any photograph at all. Those who did receive one, received a very inferior print and a very inferior frame. Sheriff Henderson said that, unfortunately for the accused, the present was not his first appearance in Court. Since 1896 he had been several times convicted for frauds of the very same kind. The sentence would be six months' imprisonment.

THE Free Enlargement Swindle.—At the Chester Assizes on Thursday last, before Mr. Justice Wills, Max Rottman, manager, Ernest Stevenson, salesman, and Mary Ellen Allcock, canvasser, were charged with conspiring to obtain photographs and money under false representations at Crewe, between February and May. There were four counts in the indictment. Mr. R. V. Bankes prosecuted, Mr. Owen Roberts defended the two male prisoners, while Mr. Wilkin appeared for the female prisoner. Mr. Bankes in opening said the prisoners were charged with a system of swindling which he was afraid was not uncommon. An office was taken at 51, Mill Street, Crewe, as a branch of the United Artistic Association, of which Rottman was manager, Stevenson local manager, and Allcock one of the canvassers. The mode in which prisoners proposed to plunder the public was as follows: Lady canvassers were sent round Crewe and invited persons to give them photographs to be enlarged free as a sort of advertisement for the association. The photos, which were particularly asked for were those of people who were dead, and which of course were held more in regard by the owners. Several people parted with photos, and these were taken to the office of the association, and when the owners of them asked for them back they were told they could not get them back unless they purchased a frame for 17s. 6d. with the enlargement. In each case when the young lady called and took away the photograph she left a receipt, which was always folded up, and hurried away from the door. This receipt purported to be an order for a frame from the United Artistic Association. It appeared that the canvassers were instructed by Stevenson to follow this method of delivering the receipts. It was a method of swindling the public on the part of three prisoners. Rottman was the head, Stevenson gave the orders,

and Allcock was the young lady who went about telling lies. Two young ladies who applied for situations would be called, and would give evidence that they were told to give these folded receipts to people who gave them photos, and to hurry out of the house before they had time to read them. Among the witnesses was a former lady canvasser named Maggie Mullock, who said Stevenson's orders to her were, "Don't give the receipts for photographs until you are leaving the door, and then get away as quickly as possible, or they may call you back and ask you for the photographs." Similar evidence was given by Cissie Mullock. William Welch, picture frame dealer, Crewe, deposed that one of the picture frames which had been sold for 17s. 6d. was worth 3s. 3d. (Laughter.) Another more massive and elaborate looking frame was shown witness by Mr. Owen Roberts, who asked what witness could sell it for. Witness replied amid laughter, "I'll make you one like it for 4s. 9d." Rose Egerton, a lady canvasser, said when she obtained employment Miss Allcock told her that there were a few lies to be told, and Stevenson said to her, "I'll tell you how many O.K.s and N.G.s you have got." The Judge: I suppose O.K. means "All correct" and N.G. means "No good." (Laughter.) This concluded the case for the prosecution, and the prisoners were called to give evidence on their own behalf. Rottman said he distinctly told the canvassers not to take the photographs unless the people knew the conditions. Stevenson said his instructions to Miss Allcock were to say the association would undertake to enlarge the photographs free if a frame was purchased at a cost of not less than 17s. 6d. Prisoners' counsel pleaded that the evidence did not prove that there was a conspiracy between them. The jury found the male prisoners guilty, but acquitted Miss Allcock. The latter verdict was received with applause. A detective stated that there had been several complaints about Rottman for similar practices. The Judge, in passing sentence, said prisoners had been guilty of gross deception upon poor people, and they would be sentenced to four months' imprisonment in the second division. Stevenson fainted on hearing his sentence.

News and Notes.

THE fifth summer meeting of the Southport Photographic Society was held on Saturday last, the place visited being Ingleton.

BY means of photography a ninth moon of the planet Saturn has been discovered, says the "New York Tribune," by the director of the Harvard Observatory.

THE Aldershot Camera Club has arranged for a trip to Windsor on Wednesday, August 10. The members will train to Staines, and proceed per steam launch to Windsor.

OWING to a slight delay in ascertaining the names of the assembled members of the Convention photographed at Derby, the key to the group we issued with our last week's number will not be given until next week.

THE Siberian Press announces that radium has been found near the village of Urovskaia, in the Nerchinsk district of Trans-Baikalia. An engineer is fitting out an expedition at Chita for the purpose of investigating the discovery and the local conditions.

THE judges of the recent Amateur Kodak Competition—Sir W. Abney, Mr. J. Craig Annan, and Mr. Frank Sutcliffe—have now made their awards. The complete list will be published in the BRITISH JOURNAL OF PHOTOGRAPHY next week.

AN English edition of the catalogue and illustrated price list of the Suter lenses and cameras is to hand from the sole British agents, the Altrincham Rubber Co., Altrincham, England. A copy can be obtained for the asking.

ALL stereoscopic workers are invited to send in their names and addresses for particulars of the United Stereoscopic Society. The entrance fee is 1s., and during the year a novel competition is held amongst its members. The secretary's address is A. J. Snow, 84, St. Andrew's Road, Walthamstow.

"Mounts Illustrated" is the title of Jonathan Fallowfield's new

price list of professional and amateur photographic mounts. The catalogue deals exclusively with mounts and mountants, and is complete. Every photographer should get a copy. A line to Charing Cross Road will secure one.

A COMPREHENSIVE catalogue of photographic materials apparatus has been sent us by Spiers and Pond's Stores, Victoria Street, E.C. It is exhaustively illustrated, and everything the amateur and professional can desire is listed. It is sent post free to anyone on application.

THE tropical summer has reminded all firms in the "dark and fields and pastures new." On Saturday last the staff at the W branch of Draycott, Limited, took their annual picnic in a and four to Brewood, one of the charming spots of the Black Country. We congratulate them, and hope to hear of the epidemic spreading.

"HOLIDAYS on the South Coast and the Isle of Wight" is the title of a neat little illustrated booklet issued by the Brighton Railway Company. It contains much useful information, and is printed in English, French, and German. A copy can be obtained free from the publisher, 30, Fleet Street, London, E.C.

A SCIENTIFIC inquiry bureau has been opened in Paris by municipal auspices, enabling any person desiring information on any scientific subject to gratify his thirst for knowledge. We can see this institution being made much use of by the peripatetic photographer, who is anxiously concerned as to "what stop" and "what exposure" to-day?

A COMPLETE pictorial record of the Grand Military Fête and Ball at Government House, Aldershot, was obtained by the photographic artists of Gale and Polden, Limited, who were specially commissioned for the work. This interesting collection will be on view at the studios in Wellington Works, and specimens will be submitted on application.

A NEW photographic list for 1904 is to hand from the Scientific Photographic Society, of 292, High Holborn, W.C. In this list a selection of lanterns, microscopes, field and opera glasses, artists' colours, etc., are included, in addition to a full range of photographic materials and apparatus. A postcard will send for a copy.

A NOTABLE personality has been lost to astronomy by the death of Captain William Noble, F.R.A.S. Taking astronomy as a hobby, he amused himself by taking observations of the less ambitious stars with a telescope, and for nearly half a century has entertained the Royal Astronomical Society by his outspoken and humorous remarks on matters which came before that learned body.

AT the Highland Agricultural Show at Perth last week photography played a prominent part. Almost every stall showed photographs of various machines or materials. The veteran Reid, of Wishaw, was hard at work with the prize animals. Brown, of London, was also busy—he was doing a great trade in postcards of prize animals, etc., and a local man, Mercer, was also seen busy at work.

WE understand that Kodak, Ltd., has undertaken, where two or more friends or more are gathered together in society, at home or at school, to send without charge a capable demonstrator, who will give instruction and explanation in the processes used in photography from the beginning to the finish, and he will do it in so simple a way as to enable hearers to start out with a camera right away and bring back successful pictures.

IPSWICH Camera Club.—The monthly meeting of members was held at the Museum on Wednesday evening last week, when a number of photographs were exhibited, the result of a recent visit to Ipswich Dock. An interesting lecture was delivered by Dr. Warburton, "Control in Printing," in the course of which he showed the various devices used by experienced photographers to improve their pictures, and also exhibited a number of photographs so treated.

M. STEPHAN LEDUC, professor of biological physics at the Faculty of Medicine of Nantes, has presented to the Société Française de Physique several remarkable photographs produced by electrical charges. His most successful method is to direct the electric charge on to the sensitive plate, so as to render it regular and symmetrical, producing designs capable of furnishing "motifs" for ornamentation, which may be indefinitely varied.

ROYAL Photographic Society.—An exhibition of photographs by members of the affiliated societies will be on view at 66, Russell Square, from Tuesday, August 2, to Saturday, August 27, daily from a.m. to 7 p.m. These pictures are selected from the prints sent in at the 1904 competition, and include the winning photographs, to which the R.P.S. plaques were awarded. Admission by application to the secretary, Mr. A. W. W. Bartlett, or by presentation of visiting card.

The Royal Cornwall Polytechnic Society's sixty-ninth exhibition will be held at Falmouth from August 16 to 20. The Bishop of Exeter, who has a summer residence on the shores of the harbour, will deliver the presidential address on the first-named day. The special feature of the exhibition will be Japanese art, and with the aid of the Japan Society and others it is hoped the collection will be representative and of deep interest. The other departments include the arts, ornamental art, and photography and its appliances.

A WATERPROOF Cement.—A writer in the "Bulletin Belge" gives the following method of preparing marine glue for making a waterproof joint:—Shellac, ten parts; pure rubber, one to three parts. The greater the quantity of rubber the more elastic it is. The shellac could be dissolved in as little methylated spirit as possible, using heat, so as to form a thick syrup; and the rubber should be also dissolved by heat in about ten times its weight of rectified turpentine and the two solutions mixed.

SOUTH Essex Camera Club Belgian Trip.—Ladies and gentlemen from London, Portsmouth, Bradford, and Liverpool have joined the club, and will leave London on Saturday, August 6th, at 8.40 p.m. An attractive programme has been arranged, including a special evening with the Belgian Photographic Association, when a lantern display will be given. The cost for the fourteen days' trip is a moderate one £5 10s., and Mr. Welford, who conducts, can still arrange for others to join. A letter or telegram to him at 166, Romford Road, London, E., will have prompt attention.

The entry form and prospectus of the Newbury Photographic Exhibition portends a successful show in September. Prizes amounting to nearly £70 in cash are offered, and the classes are both numerous and well selected. The judges will be Messrs. Harold Baker, Reginald Craigie, and A. Horsley Hinton; and the exhibition, as we have previously mentioned, is under Royal and distinguished patronage. The date of the show is given in our list of forthcoming exhibitions, and full particulars and entry forms are obtainable from the hon. secretary, Mr. E. G. Forster, Guildhall Club, Newbury.

The outing of the Ilford and District Photographic Society to Romford, on Saturday last, was favoured by splendid weather for photographic purposes. A goodly number of members journeyed down by train, while a few, in spite of the great heat, went by cycle. A round of the place was made, stopping en route to record several of the ancient houses, the church, the famous lych gate, and the hospital. This outing concluded the series for the present season, and an excellent programme is being arranged for the winter session. Attending members should communicate with the secretary, Mr. J. Cole, 160, Thorold Road, Ilford.

MESSRS. B. J. EDWARDS AND Co., Limited, have sent us from Castle Works, Ealing Dean, W., their latest catalogue of photographic materials. It is a beautifully-printed booklet, and contains in addition to the usual price list information concerning the dry plates, films, and other accessories manufactured by the firm, a complete epitome of general instructions for plate and film manipulation, many useful formulae, and a list of English and foreign dealers who stock photographic materials. The utility of this section to the photographer on tour is obvious. Many excellent half-tone illustrations are included. It is a catalogue that should be in the hands of every photographer.

TROPICAL weather is coming on again, so meteorologists are persuaded. A humorist of the Paris Boulevards says it is all M. Flammarion's fault. The latter insisted, as we mentioned in the Journal some weeks ago, on getting up a fête on the Eiffel Tower in honour of the sun. Fulsome speeches and verse were read, in which the glorious lamp of heaven was told that he was all in all to us, and that we could not live without him, which was true enough, but it

was a mistake to labour the point, although there were a great number of photographers among the party. The fact is that the sun has since been suffering from what Americans politely call "swelled head." Possibly the cold douche on Monday evening may have a beneficial effect.

STATE Aid for Science.—On Friday last an influential deputation presented to the Prime Minister various pleas for the further endowment of the universities. Mr. Joseph Chamberlain, as Chancellor of the University of Birmingham, spoke for the younger universities, while representatives from Oxford and Cambridge also gave sympathetic arguments for further State aid to these new creations. Mr. Balfour mentioned that he thought it improbable that so many representatives of learning in this country had ever been gathered together in one chamber. And certainly a list of names which included Sir William White, Sir Oliver Lodge, Sir William Ramsay, Sir Arthur Rucker, Sir John Wolfe Barry, Sir Henry Roscoe, and a number of other well-known scientists and friends of scientific work, makes it hard to believe that such a unique gathering ever took place before.

At a recent meeting of the Académie des Sciences, Paris, M. Darboux described a new mode of observing N-rays which is favourable to repetition of such experiments. Instead of simply watching the variations of brightness in phosphorescent sulphide of calcium under the rays, a method requiring good eyesight and expert observers, the experimenter only has to note the apparition of a narrow luminous ray on a background slightly illuminated. A line is drawn upon cardboard with a mixture of sulphide of calcium and collodion, and exposed to the sunlight. Then the cardboard is placed in a camera, and a ray of orange yellow light, coming through coloured glass, is allowed to fall upon it. The line of violet phosphorescence on the card thus lit by a complementary colour appears almost white, and when struck by N-rays or the material emanations from metals, recently observed by Blondlot, it suddenly brightens up.

SOME first-rate pictorial postcards have been sent us by Messrs. Hood and Co., Limited, of St. Bride Works, Middlesbrough. The majority of these are produced from half-tone blocks, and the whole of the work is done at the works. As an inducement to photographers to venture, and reduce the cost of the first outlay, this firm is starting a new method, which they call "System B," retaining the blocks themselves (under this system only), but charging them out at 33 per cent. less than their value. They rely on the hope of repeat orders to recompense themselves for this concession. A series of picture postcards of Old Newcastle are included in these sent us. They represent history both in a photographic and antiquarian sense, and it is not often authentic photographs of so great an age are able to be so satisfactorily reproduced. They are from original negatives taken over fifty years ago.

THE authorities of Framlingham College have just extended their accommodation for science teaching, and now it will compare favourably with any school in the country. Previously, the instruction in science was restricted to chemistry, and both practical and theoretical work were done in one room, the result being that the former was limited to only a few forms in the upper school. If scientific training is to be of value, a beginning must be made in the junior forms; and this was impossible under the old condition of affairs. Not only has provision been made for mere scholastic work, but a first-class dark room has been added, and here the members of the College Photographic Society are able to indulge in the completion of their special hobby. The plans for these improvements and extensions were drawn up by Mr. C. F. Bisshopp, of Ipswich, to meet the requirements of the Education Department, under the personal advice of the District Science Inspector.

A UNIQUE Photograph.—Under an Italian sky, some three hundred or more of poor folk, the inmates of Brighton's Workhouse, held a picnic at Plumpton one day last week. Towards the wane of the afternoon there was a gathering for an immense photograph. There are some among the women of the Brighton Workhouse who have lost their good looks, and among the men the rough lines of life have told upon their brows. They scoffed at the idea of being photographed. Their faces were too well-known already, they said. But there was still a grain of vanity in the most homely. By a

little wheedling and a little promise of good things to come, the old folk were gradually got together to face the camera, although some of the men stolidly smoked with their backs to the artist, and a few old ladies "didn't want no photo took." A successful negative was, however, eventually obtained, which will be all the more interesting when the fact is grasped that the united ages of the party amounted to no less than 20,102 years.

PHOTOGRAPHING Fortifications.—A correspondent of the "Morning Post" writes: "About a year ago while staying at Dover I sat down near the Castle and proceeded to sketch one of the gates, its only importance to me being its picturesqueness. I had not been occupied many minutes before a corporal from the guard appeared and informed me that sketching or photographing in the vicinity of the Castle was strictly forbidden, and I had to put up my sketch-book and my daughter her kodak. I read the other day in the papers that the officers and crews of a large foreign fleet, created, according to the expressed views of the public organs and authorities of the country to which the fleet belongs, for the special purpose of eventual war with this country, were allowed to inspect and photograph without restraint or interference the fortifications and workshops of our second principal naval arsenal. The crass absurdity of these two incidents when placed in juxtaposition needs no comment.

WHEN the memorial to Sir George Stokes was unveiled the other day Lord Rayleigh held up as an example, still to be followed, the simplicity of Stokes's experimental methods and the limitation of his apparatus to the bare essentials for the demonstrations he had in view. Professor George Darwin has well said that people are now-a-days too apt to think that science can only be carried forward with elaborate appliances, and yet many of the finest experiments have been made with cardboard, cork, and sealing-wax. Modern science has rendered necessary for many investigations highly-expensive instruments, and great laboratories are required for college purposes; but, observes Professor Darwin, "the number of great investigators has been but little increased by laboratories; and those who are interested in science, and have not access to laboratories, should not give up their study in despair." There are gentlemen living to-day who have spent almost as many thousands as Newton and Stokes spent pounds over their apparatus, and yet up to the present have not far eclipsed the two Lucasian professors.

NOVEL Colour Printing.—An exceedingly ingenious four-colour printing-machine was on view at the Dalziel Colour Press, Hatton Garden, last week. It prints perfectly to register at the rate of 900 quad royal sheets an hour, and is certainly an advance in the art of colour printing in this country. Briefly, the machine may be said to be four wharfedales rolled into one, the sheets being automatically carried over by a travelling gripper from one cylinder to another, hitting or missing any one colour as desired. Variations in colour and also in register have been the principal cause of wastage in the past, and have been responsible for most of the bad work that has brought discredit upon the Englishman as a colour printer. It is claimed that with the new machine all this is impossible, the parts working to such a nicety that an error in register cannot occur, whilst the fact that each sheet is completely printed in six seconds enables the printer to adjust any variation in the colour at once. The output per colour on the new machine—which, by the way, is a French invention—is, it is said, fourteen times that of any other, and this, too, without the employment of extra labour.

PACKING Photographic Plates on Tour.—The amateur who travels much and uses plates instead of films is frequently in trouble as to how to protect his exposed plates against injury. Some seem to think that the more they smother them in paper the safer they must be, and there are not lacking many who go the length of wrapping each plate in a separate piece of paper. When, as sometimes happens, that paper has printed matter thereon, the amateur finds on developing his plates that he has got a good deal of matter in the wrong place, for printer's ink has a strong liking for the sensitive side of a photographic plate, and will impress itself without any scruple across the choicest picture in the collection. Let the amateur eschew newspaper when he is packing his plates, or he will regret it when too late. The simplest plan of all, and as efficacious as simple, is to save the brown paper in which the plates are wrapped when

they come from the makers, and also the boxes in which they are packed. These are all the packing materials the amateur requires. The exposed plates should be put up in bundles of four, each plate film to film, and when the dozen has been returned to the box see that sufficient paper, folded the size of the box, is placed top-to make the contents fill the box to its utmost capacity. So packed will travel with perfect safety.

"ANCIENT" Photography.—According to a Paris correspondent there is a wealthy shopkeeper in the central quarter who is rather was, an enthusiastic amateur photographer. Lately he has made the acquaintance of a young man who was as ardent a devotee of the hobby as himself. While the shopkeeper thought that photography was a modern invention, the young man informed him that, like all other pretended discoveries, it was known centuries ago. An support of this bold assertion the young man produced a black parchment. He passed it through a certain process, and then a picture appeared. "It is the wife of Cæsar," he said. "But I can do something better than this. It is a papyrus which was found in a little village near Cairo, and on which is a very clear photograph of Sesostrius." The shopkeeper was greatly interested. And when he was told of the important things that would likely happen after the discovery was made known, of the honours and decorations that would fall to him, he had no hesitation in parting with a sum of £280 in order to enable the young man to travel to Egypt. He waited patiently for news of this wonderful papyrus that would make his name and fame. But the news never came. On Sunday he met his friend in joyous company at Montmartre. His first impression was to have him arrested. But the trickster said he had spent the money, and that if the shopkeeper had him arrested he would only bring ridicule upon himself by allowing himself to be swindled. The shopkeeper thought he had been fooled sufficiently, and decided to give the swindler in charge. He has, however, decided to give up photography.

Correspondence.

- * * Correspondents should never write on both sides of the paper, notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE COMPOSITION OF PAPER.

To the Editors.

Gentlemen,—With regard to the article in your issue of the 1st inst. on "Methods of Examining and Detecting the Composition of Paper," the writer is right in respect to the statement that sulphuric acid will change in sunlight, but this refers more particularly to unbleached pulp. If, on the other hand, the pulp is well cleaned and bleached white and washed clear of chlorine, it will not become yellow or go brown or yellow any more than rag or esparto when exposed to the sunlight.

The article referred to assumes that because phloroglucin is in conjunction with hydrochloric acid, that a paper immersed in the former and afterwards treated with the latter will turn black, and that this indicates the presence of wood-pulp; this is usually the case of mechanical wood-pulp being present, but if a chemical pulp only is used, that is the bleached pulp itself, the reaction mentioned is absent, and there is nothing to indicate whether the paper is made from wood, rags, or esparto, so far as this particular test goes.

It has been known to most paper-testing establishments on the Continent that all papers containing rosin size are more or less affected by the sunlight, quite apart from their composition or the material used as a fibre. Experiments made by the Leipzig Paper-testing Establishment have proved that the action of the air and sunlight on printing papers free from wood has shown a distinct change to a brown or low colour, according to the proportion of rosin sizing in the papers after they are saturated with rosin and submitted to a chemical test by which the paper is exposed to the vapour of nitric acid and then treated with ammonia. It

established clearly that atmospheric air has no influence on colour of pure cellulose paper unsized and free from wood. I have made some slight experiments with papers treated as described by the writer's article with phloroglucin, and then exposed to the air, the sunlight being very strong and the papers treated placed under a glass exposed to the sun's rays. The results were as follows:—No. 1 sample was a piece of the "Daily Chronicle"; No. 2 sample was a paper containing 70 per cent. of mechanical pulp bleached sulphite; No. 3 sample was a paper containing 30 per cent. of mechanical pulp and bleached sulphite; No. 4 sample was a paper made entirely of bleached sulphite pulp; No. 5 sample was a piece of a pure linen rag, bleached; No. 6 sample was a piece of a cheap paper pulp, bleached.

As mentioned before, these papers were all treated in the phloroglucin solution and afterwards hydrochloric acid so used to determine the presence of wood-pulp. In the cases of the Nos. 1, 2, and 3, the pulp was distinctly shown by the more or less red discoloration of the paper. In No. 4 there was no trace. No. 5 showed no trace, nor did No. 6; so that, relatively speaking, a pure wood-pulp paper under this test shows no trace of the reaction described by the writer of the article. Further, of the three pure cellulose papers, wood-pulp No. 4 was, if anything, the best colour after exposure. The use of phloroglucin and hydrochloric acid are associated entirely with the object of finding mechanical wood-pulp alone by a red discoloration of the paper treated. There are many tests besides this, but for the present it is sufficient that I deal only with the tests described to.

PETER SIMPLE.

REPRODUCTIONS FROM "SELF-TONED" PRINTS.

To the Editors.

Gentlemen,—In the BRITISH JOURNAL OF PHOTOGRAPHY last week, under the heading "Ex Cathedra," you speak of self-toning paper being admirable for reproduction purposes, and state that blocks are like it equally with P.O.P.

But also you say, as to its convenient surface for working up and facility of mounting, many others besides myself will perhaps fully endorse; but I doubt if you could get a couple of half-tone operators out of a hundred to say a good word for the average "self-toned" print. The chief defect which blocks from such prints show is exaggerated darkness of all lower tones and shadows, although P. prints occasionally (when insufficiently toned) tend to show a slight defect of muddy tones in the finished blocks, yet with the self-toning sort the defect follows almost as an inherent characteristic, for subjects showing normal vigour this kind of paper should be used when blocks are the end in view. (This very defect obviously makes S.T. paper useful when printing from flat negatives). So greatly does the use of self-toning paper increased recently that, on behalf of my firm, I have found it necessary to issue special notices advising against its use when blocks are to be made.

The failure of the half-tone block to reproduce fairly the details of brown or red inclined shadows is purely because of a want of orthographic sensitiveness in the collodion or emulsion most generally used by half-tone block makers. From the half-tone operator's point of view of processes graduated in order of desirability might be fixed as follows:—

- a. Albumen or P.O.P. as near neutral black in tone as possible.
- b. Platinotype or vigorous bromide.
- c. Self-toning paper or reddish P.O.P.
- d. (and worst). Gum-bichromate and all rough surfaces of the fuzzy variety much forward art movement type.

Any of our present day half-tone operators have a good grasp of the possibilities of modified screen distances and special stops, and some of these nothing comes amiss, from glossy P.O.P. to gum and even paper; yet, for the sake of commercial expedition, photographers would know the kind of print which will show as a block impression that sleek and smooth finished was preferred by the majority. Only by catering for this majority can the papers included in my No. 4 list above be ventured upon.—Yours faithfully,

HAROLD HOOD.

Willows, Linthorpe, Middlesbrough.
July 23rd, 1904.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration or copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

R. Wilkinson, Newbegin, Hornsea, Yorkshire. Two Photographs of East Window of Hornsea Parish Church, Showing Altar and Rails.

J. R. Brown, 11, Bedford Circus, Exeter. Two Photographs of Dr. Robertson, Bishop of Exeter.

A. H. D'Ath, 32, Bank Street, Ashford. Photograph of the King and House Party at Eastwell.

H. B. Collis, Westgate Studio, Canterbury. Photograph of an Old Print and Photographic Prints, Representing "Pilgrimage to Canterbury."

F. G. Simpson, 17, Wharf Road, Grantham. Photograph of Belton Gardens, Grantham.

F. HIGDON.—The prints are rather poor specimens of lightning photography, as half the charm of a good photograph of this kind consists of its crisp definition. Always focus for infinity, when exposing for this subject.

OPINION WANTED.—"RETLAW" says: "I should be pleased of your opinion on the retouching of enclosed print." In reply: Our opinion is that it is bad. In fact, by the retouching a moderately fair photograph has been spoilt.

"H. E. T."—From your letter it seems that you received all you bargained for, though not waiting the time you expected, so, after all, you personally have not so very much to complain of. As you wish your name withheld we cannot publish your letter.

THE "ALMANAC."—W. A. LYNASS writes: "Please send me the B. J. 'Photographic Almanac.' I am anxious to start dealing in photo goods. Could you recommend any special book to read? I know practically nothing about photography." In reply: The "Almanac" has long since been out of print. We should advise you to get some practical knowledge of photography before commencing to deal in photographic goods. "A Treatise on Photography," by Abney, is a good book.

ALUMINIUM STAND.—G. FURSMAN asks: "Could you let me know who are the London agents for the French makers of the aluminium tripods, or is there anyone in London who could repair them? Several of the catches are broken, which renders the stand useless." In reply: Most of the large dealers supply aluminium stands. Any of those who do would probably get yours repaired for you. Better apply to those who supplied you with the stand in the first instance.

TRADE DISPUTE.—"MOUNTS" says: "Having been trading with a man for enlargements, he sent me one lot on mounts as per order, but the remainder he sent on a smaller mount, and the work was much inferior; and as I had ordered frames to fit the photos it has made them useless to me. I have returned the batch and dispute my liability. Am I right?" In reply: If the order has been wrongly executed you have acted rightly in returning the pictures, and you can refuse payment until others are supplied.

COPYRIGHT QUERY.—"HIGH GREEN" writes: "(1) My operator was ordered by me to take negatives of which it was desirable to register the copyright. If the operator has agreed that the

copyright in all his work shall belong to me, whose name must be inserted in the fifth column of Registration Form as author? (2) Would the insertion of a wrong name be a false entry and invalidate the registration?" In reply: (1) Register your name as the owner of the copyright and that of the operator as the photographer. (2) Yes, in all probability.

COPYRIGHT QUERY.—J. A. COLEMAN asks: "Is it necessary to have 'Copyright' printed on postcards which I have had made and which I am selling? I have got them entered at the Copyright Office, but I have not the word 'Copyright' on the cards or anything to show they are copyright. I am putting the cards up for sale in packets of twelve each. Will it be sufficient to have 'Copyright' printed on packets only? I will also be selling them singly as well as in packets, and wish to keep the trade to myself." In reply: It is not at all necessary that the prints be marked "Copyright."

WOODBURY TYPE.—J. H. STORR says: "I should be much obliged if you would refer to the back numbers of your journal and see if you have one giving full details of Walter B. Woodbury's 'Woodbury Type Printing Process' by bichromate of gelatine. I believe it was published early in the '70s, somewhere between 1871 and 1874, and, if so, I should be glad of a copy; or if published in any of the year-books." In reply: We have no back numbers of the Journal so long ago as the dates you mention. You will find the Woodbury type process, with working details, described in Burton's book, "Photographic and Photo-mechanical Printing Processes."

STAINED PRINT.—"T. W." says: "(1) I have a gelatine photograph to copy which has ink marks across the face. Is there anything that will remove same without injuring the photograph? (2) In the B.J. of March 27, 1903, you answered my query in reference to wrong name of photograph taken for publication. I wrote as you advised, and received a letter of apology promising to alter in next edition. The second edition is now issued, and I find the name is not altered. Can I do anything further in the matter?" In reply: (1) We fear there are no means of removing the ink without injuring the print. The best way will be to copy the picture as it is and then touch out the marks in the negative. (2) If you hold a copyright in the picture you can restrain the sale of it.

COPYRIGHT QUERIES.—"G. P." asks: "(1) Can it be that a photograph is copyrighted when 'Copyright' is not printed nor written on same? (2) Can photo in question be painted in full size by anyone without permission of photographer who is claiming copyright without infringing copyright if it really was copyrighted? (3) If any painting is added on to the enlargement of my photograph which really is copyrighted, or if the photograph is altered in any way by enlarging same, can you call this infringing copyright, and can you sell same altered, enlarged, painted, to the public? In reply: (1) Yes, certainly. It is not necessary that the picture be marked "Copyright." (2) Decidedly not. (3) No, certainly not. The copyright would be infringed, and the infringer would get himself into trouble.

BICHROMATE TROUBLE.—"SUBSCRIBER" writes: "Can you offer any advice as to the cure or alleviation of the bichromate evil in carbon printing? I have terrible trouble with my hands, itching, etc., and nothing seems to do any good at all. To develop one print sets them off, and up to my elbows is one mass of spots and blotches, which constantly bother me. I should esteem it a great favour if you could give me any advice." In reply: The best advice we can give is for you to relinquish working the process. Then the evil will cure itself. The next best thing is to do the work in indiarubber gloves so that the bichromate does not come in contact with the skin. The following lotion will greatly alleviate the irritation:—Alcohol, 5 ounces; glycerine, half an ounce; carbolic acid (pure), one dram. Should this cause a great deal of smarting dilute with a little water, but it is better as it is.

INFRINGEMENT OF COPYRIGHT.—"VELOX" says: "A few months ago I had a photograph made copyright by you, but have received no form or anything to show it is copyright. Is a form neces-

sary? Since it was made copyright a certain party produced the picture on postcards, and in booklet form, without asking permission or even printing my name on the back of it. I intend suing for damages. Would £5 5s. for the block made be too much? I should like your opinion as to what damages I ought to claim, as it is a very popular picture. In reply: As the picture has been made copyright without issue for penalties on every copy made for damages, and in junction restraining further sales and forfeiture of all negatives, etc., and all copies. You can obtain at Stationers' Hall for 5s. a certified copy of the entry in the register which will be taken as *prima facie* evidence in a court of law that copyright has been registered. You had better consult a solicitor who is well versed in copyright law. He will advise as to the amount to claim.

LANTERN QUERY.—"L. F." says: "I have a magic lantern Petzval portrait front lens (achromatic), adjustable rack and pinion for focussing, and compound condenser 4 in. diameter. I have fitted an incandescent gas mantle in the place of the ordinary three-wick burner. I have got a clear enlargement, size 10 in. by 8 in., by putting a negative in the opening which is made for the lantern. I can focus quite sharp only in the centre or thereabouts (*vice versa*) round the outside only. I have fixed everything quite parallel and perpendicular, and have moved the various distances from condenser. When I show pictures 6 ft. by 6 ft. exactly the same results occur. I shall be glad if you will tell me the cause. Which way shall I be able to get the best results—by daylight or artificial?" In reply: What you say we should think that the objective has a round field. Try another lens, say one constructed for carte-de-visites; or, if you can afford it, get a better lens altogether for enlarging, such as one of the anastigmats with flat field. You will probably find it will give you the best enlargements, using the lens with which you obtained the original negative.

STUDIO QUERY.—"STUDIO" says: "I have recently opened up a studio, and take my portraits in a room as per enclosed plan. I find in practice that there is a deal of sameness in my lighting, viz., ¾-face in shadow I use a sheet reflector. Would a more powerful reflector be advantageous? How should you place your sitters so as to get good soft lighting? It appears to me that my light is too strong near the window, and if I get far away I have to give too long exposures. Would there be any advantage gained by removing the bay-window and inserting ground glass, or will it throw too much light on head of sitters? You will notice the window is already level with ceiling. I shall be glad of any useful hints as to effects I can get by placing sitters at any part of the room by opening folding doors." In reply: You have no difficulty in getting good portraits in such a room, though it is scarcely adapted for professional work. Should advise you to place the sitters further back than in the sketch, and soften the shadows with a white card. We do not see that any advantage would accrue from removing the lead. Cannot you get some professional photographer to give you a few lessons in lighting?

NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Fancy Portraits.

The release of a famous convict whose death sentence fifteen years ago was changed for one of penal servitude has given occasion for the publication of many fancy portraits. We use the word "fancy" for the very good reason that these line drawings, which are published in various newspapers, have so little in common with one another that we should not know that they were intended for the same unfortunate woman unless they bore her name. But what we should like to know is the source from which the artists obtained their inspiration—that is to say, if they had any. Surely not from a photograph, for in that case we should find some correspondence in pose, if not in feature, between these various pictures. Besides, it is a fact that at the time of the Maybrick trial photographs of the accused, although much in demand, were not to be had. To be exact, there was a photograph to be purchased at the shops, which, we believe, had a large sale, but it was not a photograph of the lady herself. We have recently had an opportunity of examining this portrait, and although it might, and no doubt did, pass muster with the great non-observant mass of persons, it could not fail to arrest the attention of a critical eye by reason of its doll-like and unnatural appearance. But it is the hands which give the show away. This portrait of Mrs. Maybrick, which was sold when everyone was interested in the details of her most sensational trial, was taken from a waxwork figure. The persons who went to the expense and trouble of meeting a demand for a portrait in this way deserved their reward, and if the waxwork had been a little better done the secret might have remained undiscovered.

* * *

Tit for Tat.

Some time ago a New York lady had reason to complain of the action of a patent food company who paid her the compliment of selecting her portrait as a kind of trade-mark to lend attraction to their wares. We are not told whether the lady was exceptionally handsome, or whether she was simply "fine and large," and thus gave a silent if unwilling testimonial to the nourishing properties of the food in question. However that may have been, she objected to figure among the babies of abnormal size which usually stand as sponsors for this kind of sustenance. She brought an action against the company, which was heard before Judge Parker, who decided that the lady had no property in the photograph, which seems to have been the result of a snapshot taken without permission, and she was non-suited. But now she is radiant, for accident has brought sweet revenge. This same Judge Parker has been nominated Democratic candidate for the Presidency, and swarms of photographers have been, and now are, invading his premises with the

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published in December next. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued in two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc.

hope of securing his likeness without the formality of asking his leave. He and his family very naturally resent this intrusion, and are doing all they can to stop it. The lady whose portrait adorns the patent food tins writes to the papers in high glee, and sententiously remarks that sauce which is good for a goose is also applicable to a gander. Of course, she could not have said this openly at the time that she lost her cause, or she would have been guilty of contempt of court, but doubtless the pleasure does not suffer by postponement. It will be gratifying to all photographers to learn that a lady who was at one time so opposed to the work of the hand camera is now such an enthusiast in its favour.

* * *

Copyright.

Not a few of our readers, we imagine, think that the subject of copyright in photographs has been dealt with *ad nauseam* in these pages during the past few months, and that every reader would be fully conversant with copyright law as it applies to photographs, particularly as the Copyright Act itself has been printed in full in the almanacs for several years past. Notwithstanding all this, we are continually having to reply to correspondents through the "Answers" column to the most trivial questions on the subject. Only last week we replied to no less than five queries relating to copyright, all of which in effect have been replied to over and over again, as well as being fully dealt with in editorial articles. Is it that people pay no attention to what they read, and when they imagine that they have suffered some wrong at once appeal to us? Two of the five queries last week relate to whether a photograph, the copyright of which has been registered, must necessarily bear the imprint "Copyright" upon it? Over and over again have we replied to this question that it is not at all necessary; yet it is being continually repeated. From one of the queries in our last issue it would seem that the writer thinks that it is possible to evade the Copyright Act because the photograph is not marked "Copyright." Further, that if an enlargement is made, and some alterations made in it, that the law can be evaded. It certainly cannot without rendering the infringer liable to all the penalties of the Act, and rightly so too. No one has a right to appropriate to himself another man's property, whether it be his copyright or his purse. It is often asked how is one to know whether the copyright in a photograph has been registered or not unless it is marked with the word "Copyright"? The only way that this can be ascertained is by searching the register at Stationers' Hall, and anyone who copies a picture without first ascertaining whether it is copyright or not does it at his own risk. As a matter of fact, copyright in a photograph exists from the time it was taken, and is the property of some one, though no action can be taken for its infringement until it has been registered at Stationers' Hall, as has frequently been said before in these pages.

Photographic Apparatus as Personal Luggage.

Last week, in "Ex Cathedra," we commented upon a case before the Holywell County Court, in which the plaintiff sued the L. and N.W. Railway Company for the loss of photographic apparatus enclosed with passenger luggage. We give the decision in this somewhat important case in another column. The Judge is reported to have made the remark that nine out of ten passengers now carried cameras among their luggage, and the remark is doubtless correct with regard to tourists. But is it wise, under any condition, to pack the apparatus with one's personal luggage when it has to be consigned to the tender mercies of the luggage-van, particularly when one sees how carefully

(?) personal luggage is handled by the railway porters. For our own part, we always take our apparatus with us in the carriage, and never trust it to the care of porters or indeed out of our sight. Plates, if we have many, we may sometimes pack in our portmanteau, but no more than we can conveniently take with us in the carriage. Then we always know that our apparatus at least is safe. Those who have travelled on the Continent have not failed to notice the way that passengers' luggage is handled by the officials on its landing, and also its transhipment on the different railways. In the old plate days, when the paraphernalia that had to be taken on a photographic tour was very different from what it is now, the careful worker always took his camera in a watertight bath, plates, and all fragile articles in the carriage with him. The only things he would entrust to the luggage van was the dark tent, which was a bulky affair, and the tripod stand. Apparatus is now of such a portable kind that even a whole-plate camera and its accessories will easily go into a moderate-size Gladstone bag, or be packed in smaller sizes into a small handbag, that we should all be able to take with us. All photographic tourists, whether at home or abroad, should take their apparatus, and such plates as they conveniently can, with them in the carriage in which they travel. They will know that they are safe when they arrive at their destination, wherever that may be.

* * *

An Unsuspected Cause of Unsharp Negatives.

During the past month we have had a very trying weather that has been very trying to photographic cameras such as those of the box and magazine form of fixed focus, or with a focus that expands when wetted and contracts when it dries. Many cameras of the cheaper kinds are made of quite unseasoned wood, and usually covered with an imitation leather. If with such a camera the owner happens to be caught in such a shower of rain as we have had lately, the apparatus will have got a pretty good wetting. The imitation leather will have become saturated and will communicate the moisture to the wood, which, of course, will expand, more or less, thus increasing the length between the lens and the plate. On the other hand, the camera may be carried a long distance on a hot day with the sun upon it, in which case the wood will shrink, and so shorten the distance between the lens and the plate, and so alter the focus of the lens. It so happens that in order to secure rigidity, cameras, as a rule, are built with the grain of the wood crosswise, and it is in this direction that the expansion and contraction is the greatest. It is in the commoner forms of hand cameras that this expansion and contraction is the greatest, though its effect is the least noticeable in the negative for the reason that the lenses usually supplied with them are single, and the largest aperture only about f11. With such the alteration of focus caused in the way alluded to is not very noticeable, but if such a camera be fitted with a high-grade lens worked with its full aperture, which we will assume to be f6, or larger, the case may be different. With such a lens at its full aperture there is little so-called "depth of focus" and a difference of, say, the twentieth of an inch, either way, will materially interfere with the microscopic sharpness of the image, and this will be made more manifest if the negative be enlarged. We have been speaking of fixed focus cameras, but it also applies to those of the magazine or box form with focussing index, as that does not alter the conditions unless allowance be made for any supposed expansion or contraction. Cameras with bellows are of course, so much affected by the expansion and contraction of the woodwork as those of the rigid type.

vandalism. Every place in this kingdom which has or had anything of historic or archaeological interest to show in the way of a building has at one time or other suffered from the ignorance or cupidity of its inhabitants. In past times an old ruin, it might be a feudal castle or an abbey, was looked upon as a quarry from which to get stones for new building operations or metal for the roads. It is on record that the grand old Castle of Rochester, one of the finest within easy reach of the Metropolis, was at one time sold to a contractor who, after stripping it of its facing stones, failed to make its further demolition a paying operation owing to its solidity. If dynamite had been then invented Rochester Castle would now have been known only by tradition. But in these more enlightened days people, however interested they may be in such destructive work, have to think twice, or more than twice, before they put theory into practice. For there are societies of various names which are doing excellent work in guarding buildings which we may regard as national heirlooms. The worthy members of these bodies act like so many amateur vigilance officers, and warn offenders off directly they see any signs of wrong-doing. We may be quite sure that photographers generally will support these efforts to preserve, as far as possible, these links with the past, for photographers have the instincts of artists, and do not like to see everything that is picturesque swept away from our far too prosaic thoroughfares. There have been two instances lately of the zeal of those who are endeavouring to protect the work of past generations. All who know the High Street at Croydon will remember the picturesque building known as Whitgift Almshouses. It seems that these houses are rather in the way of the electric trams, and the Croydon Council want to pull them down. Then arises "The Croydon Antiquities Protection Society," and a bother begins—in the columns of the "Times." A Croydon Councillor seems to think that the building is not of much account because it is built of brick! Surely he forgets, or does not know, that many most interesting buildings in this country are built of the same material—for example, Fenham Hall, Suffolk, which dates from the year 1260; the fine old ruin of Hurstmonceaux, of about the same period; and lastly, that splendid piece of Metropolitan brickwork, the gate of Lincoln's Inn, in Chancery Lane, upon which Ben Jonson is said to have worked as a labourer. It is clear, therefore, that we cannot think lightly of a building because it is formed of brickwork, and we trust that this consideration will not have any weight in the proposal to demolish the almshouses at Croydon. The other piece of vandalism, which has aroused the ire of another society, is the removal of the original cast-iron lamp standards from Waterloo Bridge and the substitution of a design not half so good, but better adapted to modern electric lighting. This last is a small matter compared with the threatened destruction of a building, for the old designs are still preserved on paper, and can be re-cast with modifications to suit modern requirements. It is comforting to think that the spirit of destruction is being kept under such rigid scrutiny.

PHOTOGRAPHERS AND WEATHER.

EXCEPTING the agriculturist there is, perhaps, no member of the community to whom a knowledge of the weather and its apparent vagaries would be more important than it is, or would be, to the photographer. Even in these days of bromide printing, he must take count of the probable atmospheric conditions before laying out plans for his day's work, while, if he project a day with his camera in the country, he is at the mercy of wind and rain; and, starting out apparently with everything in his favour, may return home without having made an exposure through a strong wind having arisen to prevent his working among foliage, or with camera and temper spoiled through an unexpected rainfall, such as that experienced at the close of the Dovedale Convention excursion. All through want of power to read the weather signs! We do not expect weather forecasting ever to be brought to the level of negative-making—to the press-the-button-and-we-do-the-rest style of thing; but we do hope for an improvement on that barometer tapping which with so many of us represents the sum of our acquaintance with meteorological forecasting. We are always pleased when, if the usual crowd have not done their own tapping before we essay our weather chances, the pointer goes up in the direction of "set fair," whatever that may really portend; but if, as is often the case, the finger remains motionless, we usually feel as "stuck" as the finger itself when we want to know what it all means. If anyone will refer to his Whitaker he will find an excellent article on "Forecasting the Weather," in which an excellent *résumé* is given of the possibilities and the limitations of the most recent methods of prophesying about the weather, and the page of matter is well worth perusing. It will be found more than a step beyond those popular beliefs about a rosy evening sky portending a fine day on the morrow, or swallows flying low foretelling rain, occasionally useful though they be. A little time given to thus studying the subject will often be well spent, and a pleasant novel study opened out; for we have often found those that have taken the matter up in the true scientific spirit to become thorough weather enthusiasts. More complete survey of what is at present known about the cause of these atmospheric changes must, of course, be sought in larger treatises, not the last excellent of which will be seen in the International Series, in the one entitled "Weather," by the Hon. Ralph Abercrombie, and its perusal is well worth the outlay. It will soon be noticed that what is relied upon nowadays is an extended series of observations, at as large a number of places as possible, and the height of the barometer, direction of wind, moisture in the air, and so on. Obviously, no private observer, even one possessed of ample means, leisure, and the needful enthusiasm, could, individually, undertake the collection of the necessary data, but the Meteorological Office forms the organisation that is needed, and the joint results of the continuous observations of its staff are focussed in the forecasts we read in our morning's paper.

In connection with these and all such weather predictions hitherto available there is one most important factor to reckon with, that is to say, special local conditions. But even of this Abercrombie writes: "If we watch the actual occurrence of any local peculiarity of weather, we shall soon find out that in every instance it is the intensity, and not the general character, that is altered," and again "It is from the observation of innumerable cases that we are enabled to lay down the general law that the primary character of all weather is given by the general distribution of the surrounding pressure; the local variation modifies, but never alters, this general character."

ACCORDING to M. Jean Becquerel the N and N1 rays consist each of three elements, of which two are influenced by the magnetic field, and similar to the "alpha" and "beta" rays of radium. The author also finds that all bodies, compressed or diluted, as well as the brain and nerve centres, are radio-active. His experiments, which were described to the Academy of Sciences, extend the field of radio-active phenomena.

As examples of this local variation, which anyone can see for himself, we may note that, "Roughly speaking, if a range of hills under about fifteen hundred feet obstructs the prevailing westerly wind, the greatest amount of rain will fall on the east side of the range. . . . If the range is over fifteen hundred feet . . . the greatest rain will fall on the west side of the hills. No rule, however, can be laid down except in very general terms, for every hill, every valley, has its own local peculiarities in the manner in which it develops rain with different winds." Another local condition is the presence of a tidal river. When the weather is threatening, but no rain falling, it will often happen that after the tide turns to rise, and the stream is running upwards, that rain will fall quite locally without extending far from the river banks. Similarly, in calm weather at a similar turn of the tide, the general direction of the wind will be much increased in force and gustiness. But as it is not our intention to make this article a treatise on how to forecast the weather we will draw attention to the possible promise of future benefits in that direction.

In 1902 a commission was appointed "to inquire and report as to the administration by the Meteorological Council of the ensuing Parliamentary grant," etc. This Report has just been issued, but so far has had little public comment. As to the Report itself, we extract portions of two paragraphs. After pointing out the necessity for further grants to assist the progress of meteorology, it says, on account of these restricted means, "it would be better to circumscribe the operations of the Council than to expect them to undertake investigations for which they have not adequate means." Further we read, "The present constitution of the Meteorological Office was never regarded by the Royal Society as a permanent one, but as a temporary measure till some other organisation should be carried out. We regard this as a favourable opportunity. . . ." Everyone interested in the subject will agree with the final paragraph of the recommendations: "The evidence before us has shown conclusively the importance of further scientific research, for which we trust that funds may be forthcoming in the near future." If the recommendations should really be carried out, the future promise of weather forecasting, especially in view of what wireless telegraphy has already accomplished, is most promising. The chief difficulty, to our mind, lies in the machinery for the financial aspect of the proposed changes. Politicians, we are afraid, would call it "gerrymandering." It is proposed to take out of one pocket and put into another. A net increase of £449 only is suggested, though the Post Office is to be mulcted in £2,000 a year, which will not be shown in the usual accounts. It is true that this is to be for increased postal and telegraphic services for the "good of the cause," but the authorities are not very apt to allow any expense to be incurred which would reduce their big surplus—a surplus which many argue ought not to exist, their views being that every penny not expended one year should be utilised to reduce the cost of such a public service in the next year. Be that as it may, our readers will join with us in the hope that the public meteorological service of the country may soon be put on such a basis as will render them of suitable value to working photographers.

PHOTOGRAPHY can scarcely be put to better educational use than in illustrating books on geography for schools. In "The British Isles," a volume of the "Regional Geography" series, Mr. J. B. Reynolds has employed it suggestively. In other respects this geography book is commendable, its elementary lessons on geology being well planned and illustrated.

ELEMENTARY THREE-COLOUR WORK.

II.

LET me at the outset apologise for some typographical errors in my notes in the last issue; they are my fault, I think rather the consequence of my living in a delightful corner spot where posts are uncertain, so that corrected proofs do not reach the printers in time for correction. The only which really calls for correction is the name of the red dye this should read "Bieberich," and not "Bisberich." There is one or two grammatical errors which are obviously due to want of proof correction.

Supposing that the student has determined on his screens and plates—and I may interpolate here that, although screens given are adjusted for the Lumière panchromatic plates they may be used for three different plates, namely, Lumière ordinary, the Lumière green sensitive, and the Lumière panchromatic, and I venture to say with equally good results. Personally, I prefer the three different plates. Theoretically the third plate of the above should be the Lumière red sensitive, but this never gave such clean results in my hands as the panchromatic. I would defend myself, if it be necessary, against any possible charge of favouritism in naming the plates. I have no interest, direct or indirect, in the same, they are simply the plates I adjusted the screens for: Ilford chromatic, the old slow kind, can replace the green sensitive, but an adjustment of the screen is necessary, green constituent being slightly increased. I regret that I am unable to say positively the exact adjustment, but I believe it is a decrease of the picric acid stock solution to 40 parts. This seems a somewhat involved procedure—namely, to reduce yellow constituent to increase the acid green, but the result is obvious on a moment's thought, because decrease of yellow allows more blue green to act, and thus is equivalent to increasing the acid green. My notes on the exact ratio unfortunately, at present, un-get-at-able.

There are two pitfalls against which the practical worker should be warned, and the most important is to avoid judgment of the correctness of results from an examination of the negative. To me there is absolutely nothing more misleading, provided and this is an important proviso, you do not know the subject and I venture to state that no operator can possibly know his subject so well as to be able to tell on sight exactly how much of each primary colour, or I will rather say how much of each printing ink, is to be laid down to reproduce his original. When a man says he can do this I know, and do not think, that he is a bumptious ass, and does not know his work. There is nothing more misleading than the appearance of the negative, and that which looks under-exposed and too bare is frequently correct. This is particularly the case with the red print negative, that made through the green screen; my experience though limited to experimental work, is that the negative through the green screen always looks under-exposed, though in fact, there is far more red—and I am talking of painting now—than one would suppose in most subjects.

When a chart, such as that issued with Hübl's book, is taken as a subject for adjustment of the screens, we know from Hübl's directions the action of the control colours, and we can adjust our screens till the desired effect is obtained, and if this is done, then, no matter how the subsequent "subject" negatives look, we know they are right.

This brings us to the second pitfall, and that is that of the printing inks. Provided the theoretically correct inks are used—that is to say, those inks which will exactly fill up the vacuities left on the three negatives—a given set of screens will act satisfactorily, but I know of no two sets of trichrome inks which are exactly alike, and this can only be determined by a system of colour analysis; nor is there, so far as I am aware, one

of inks theoretically correct and stable. All three inks may be correct when in full tones, but that does not necessarily imply that they are correct in half-tones or fine detail, nor that the mixtures by dots or mosaic, as in ordinary half-tone printing, are the same as when three complete films—that is, films unbroken by white spaces—are superimposed. This subject has been but little dealt with, and necessitates a colour analysis in various states of dilution of the inks, which no one has yet undertaken. It is obvious therefore that just any set of trichrome inks will not do, and until we get the theoretically correct inks, the filters and plate sensitiveness must be adjusted to the inks.

It has been suggested that, to test the correctness of the colour rendering in the negatives, the operator should print on chromated gelatine, develop the results, and then stain and superimpose; in fact, that the superposition of gelatine reliefs, stained with aniline dyes and viewed by transparency, can prove the correctness of the negatives. This may be so, and I have used the negatives made for photo-mechanical work for the stained film process, but if it is put forward as a test then I say that the operator who adopts this is going to strike trouble, and badly. The two results are so totally different in appearance that the one is no guide to the other, or, rather, one may be very easily misled. The theoretical difficulty, of course, is that the absorptions of the staining dyes may not correspond to the absorptions of the printing inks; in fact, the odds are against their doing so, and thus trouble may arise; and, further, whilst one may fake the stained film by reducing or intensifying the staining, and different depths of staining are obtained by variations in exposure, we cannot, as a rule, fake our printing inks to correspond.

Reverting to the topic of making the filters, it is, of course, absolutely necessary to cement them together for practical work, though for experimental work this need not be done. When a filter is made up of two colours, such as a green and a yellow, for instance, it is advisable to stain one gelatine with the green and the other with the yellow; then, if the results are wrong, it is easy to alter the staining on one or the other; whereas, if both dyes are combined in one staining solution, a fresh filter and solution must be prepared.

Cementing the filters is a nuisance, unless one goes the right way to work. I have found that the hard baked Canada balsam, as supplied for micro work by Merck, is the most satisfactory, and this is just made fluid with xylol, and used warm. The filters should be warmed up and a fairly large pool of the balsam put in the middle of one, and the other lowered gently on to it, contact being made first by one corner, thus avoiding air bells; as soon as the two are in contact press down, and allow to remain on a levelled slab till the balsam and glass has cooled down, then clip with the strongest bulldog metal clips you can get, and dry. When first cemented the filters have a happy knack of sliding apart, hence the necessity of the level slab. After cementing they should be left at least three days in a warm place, then the edges cleaned and bound up.

The glass I have always used is a special white patent plate, made by Pilkington's, about 1-16th of an inch thick, and one can from a dozen or more pieces easily select a few almost perfect squares. The gelatine should be one made for emulsion work, its hardness or softness is immaterial, and so is the quantity as long as there is enough to carry the given quantity of dye; its solution should be well filtered, and if a very thick film is used and no special drying arrangement be handy, some preservative should be added, such as thymol, phenol, or xylol, otherwise the characteristic pit of the microbe makes its appearance. Quite recently, in using a new sample of gelatine, I struck a trouble that hitherto I had not noticed, and that was a rapid fading of the colours; and on testing the gelatine very

strong, and distinct traces of sulphurous acid were found, the acid being used to bleach it in process of manufacture; since this I have tested another well-known make of emulsion gelatine, and found also sulphurous acid present; therefore a thorough washing of the gelatine by repeated soakings in water is advisable.

In developing trichromatic negatives it is important that the same should be carried to the same point, and for this reason Mr. Watkins' factorial system is not only valuable, but also because there is no need to keep on examining the negative to see whether it is sufficiently developed; there is therefore less chance of light fog. Besides this, the appearance of the three negatives is, as a rule, so different that one is easily misled as to whether they are sufficiently developed or not.

E. J. WALL, F.R.P.S.

LARGE AND SMALL STOPS, ETC.

By the AMATEUR OPTICIAN.

Few subjects are so continually interesting as those dealing with indoor architecture and the best way of photographing the same. Now imagine a room or office about 18 ft. by 20 ft., with a big bay window in one of the narrow ends, this window supplying the only illumination, and ample enough for all business purposes. The problem is to photograph the room from a corner opposite to the window, to show as much of the room and contents as possible, and the window, with the minimum of halation in the latter.

The window was fitted with blinds of some yellow material, and, naturally I think, it seemed to be the best course, having made the best possible focus, to pull these blinds down during a fairly long exposure, to then cap the lens, draw up the blinds, and expose for a few seconds more—backed plates understood. As a matter of fact, an exposure of three minutes was given with the blinds drawn and five seconds with them up; an "Imperial" backed plate was used 1-1 pl. size, the lens a 1-1 pl. W.A.R., F.28. The result was satisfactory enough from a business point of view, there being ample detail, without undue halation, but it occurred to me to try another in a different way. The camera was placed as nearly as possible as before, the picture focussed, the blinds drawn up to full extent, and four minutes' exposure given with F.45. Prints from both negatives have been sold to the parties with entire satisfaction, and as a matter of fact no one notices any difference except that which might arise in the printing. I think the method adopted of shielding the window when blinds are available, during a part, at any rate, of the exposure, would be adopted as an orthodox and rational way out of a somewhat difficult position, but results prove that the second and alternative method is worth attention. I am under the impression that in pin-hole photography, under similar circumstances, halation is absent! It is certain that with the lens very much stopped down (F.45 was scarcely small enough) the picture as viewed on the screen is much more evenly lighted, or rather the volume of light from the window is much subdued, to the betterment of the whole. There is some virtue in the small stop; several friends of mine, old stagers like myself, went in rather strongly twenty years ago for very small stops, getting them made to order, and we gave long exposures sometimes—very long to more modern ideas—but I cannot remember that we were bothered much with the halation bugbear.

PHOTOGRAPHIC Convention of the United Kingdom.—Many of our readers—more especially those who are members of the Convention—will be pleased to hear that Professor John Joly, F.R.S., to whom the presidency for next year's meeting in Dublin was offered, has accepted the position.

THE PRICE OF PHOTOGRAPHIC MATERIALS FIFTY YEARS AGO.

THE celebration of the Jubilee of THE BRITISH JOURNAL OF PHOTOGRAPHY has lately brought photographers and photographic methods of past years into prominence, and the following comparison of the relative cost of photographic chemicals fifty years ago with current prices should prove interesting.

A catalogue in the writer's possession of photographic apparatus and chemicals, dated July, 1851, gives a complete list of the prices the unfortunate photographer had to pay for his materials, etc., at that time. In 1851 Daguerreotype still held the field and collodion was only just coming into use. The wet plate negative which Scott Archer soon afterwards brought to such perfection was not then in vogue. Daguerreotype materials consequently occupy the chief part of the list. Cameras are listed at very reasonable prices considering the vast quantity of mahogany a camera contained in those days. A quarter-plate camera for Daguerreotypes cost £2 15s., including a single achromatic lens. A quarter-plate camera for taking calotype pictures is quoted at a cheaper rate, viz., £1 10s. Lenses were also supplied at a reasonable figure. A single achromatic lens of 7 in. focus could be obtained for 9s.; mounted with rack-and-pinion adjustment £1 5s. Considering the quantity of the materials and workmanship these figures compare favourably with those of the present day.

Passing over the mercury-box, thermometers, etc., etc., required for photography à la Daguerre, the list of chemicals affords very satisfactory reading for modern photographers. Hyposulphite of soda is quoted at 3s. a lb., To those photographers who purchase their hypo at 9s. per cwt., 3s. seems a staggering price to pay for one pound of the fixing agent.

Cyanide of potash, which was formerly much used as a fixing agent, cost 6d. an oz. Half a pound of this chemical is now obtainable for that price; but, as cyanide is now only used by wet-plate workers, this reduction of price does not affect the bulk of photographers.

Bromide of potash was also an expensive item in the old days and cost 4s. an oz.; but the restraining effect of bromide had not then been discovered, and this substance was only used in the preparation of plates and papers.

Chloride of gold (15 grain tube) cost 3s., so there has been no great reduction of price in this instance.

Silver nitrate is listed at 5s. an oz.; it now costs about 2s. Collodion cost 1s. an ounce, which is about three times its present value.

Another chemical, gallic acid, now rarely used in photography, cost 3s. 6d. an oz. A pound can now be obtained for the same money.

Sulphate of iron, nitric acid, ammonia, and iodine have all depreciated in value to half the amount formerly charged.

If the price has decreased, however, the number of photographic chemicals has increased in the same proportion. The total list of substances included in the 1851 catalogue only number 39, while in one of the latest catalogues the photographer has the choice of 300 chemicals. The list concludes with the remark that "the prices are subject to variation, but at all times the lowest price possible is charged." If these figures give the lowest prices, one cannot help wondering what the highest charges would be.

In addition to prices the old workers were handicapped by the necessity of using a lot of expensive apparatus in order to prepare their plates, and a dozen copper plates silvered for sensitising cost 14s. for quarter-plate, 30s. for half-plate, size. These silvered plates were of course used for Daguerreotypes. As the image was positive, a fresh plate was required for each photograph; so for amateur workers photography must have been a most expensive hobby.

Beginners who did not feel capable of selecting their own materials were supplied with a complete set of apparatus for

taking quarter-plate Daguerreotypes, including all requisites for one dozen photographs, for nine guineas. All the necessary materials for calotype photography was obtainable for a modest sum of four guineas.

The whole list of 1851 photographic materials consisted only eight pages; one of the latest catalogues issued has considerably over a thousand pages, and each page of the latter is more than twice the dimensions of the former publication. The price of materials and difficulty of preparing the plates had one advantage over the present cheap and easy methods. The photographer in those times was a careful and methodical worker, and did not object to giving time and trouble to operations. The results that were obtained by the old workers were often of the highest order and would serve as object lessons to many present-day workers. J. I. Price, F.R.P.S.

THE NEW "STEADMAN" SYSTEM OF EXPOSURE AND PLATE SPEED MARKINGS.

A CORRECT exposure is a correct latent image prepared in the emulsion. This correct latent image can be made only by giving during the actual exposure a certain length of time with a certain diaphragm. All the elements that enter into the making of exposure can but alter one or the other of these two things, i.e., the length of time or the size of the diaphragm. By taking a simple numerical statement of the light's intensity as a convenient basic exposure, and in each case obtaining that numerical length of time by actually measuring the length of time that the intensity requires to perform a certain fixed labour, the factors of intensity that have always entered into the exposure tables, even in the last one out, that of the house of C. Goerz.

This intensity numeral must not be a factor, but a simple statement of intensity or value, just as the expression 60 degrees Fahr. expresses an intensity, and 3 feet expresses linear distance. It is this simplicity that will solve the problem of photographic exposures and make simple mathematics out of what is now the real "bugbear" of photography. In order to give a practical measure or standard fixed labour for the light to perform it has been necessary to select solio paper, as it so happens that there is no other sensitive paper that can easily be obtained at the present time in every country of the globe. And standard is not a standard in truth unless it is susceptible of universal and worldwide utilisation.

The "solio time" of an illumination existing at the surface of solio paper is the number of seconds or length of time that is required to bring it to a just plainly observable tint when looked at in contrast to the original colour of the paper. The tint is to be taken through a small hole, about $\frac{1}{4}$ or $\frac{1}{2}$ in. square, so that the rest of the strip will be protected from the light while the tint is being made. This hole may be cut in the thin, opaque cover of a common note-book. The book should be held at the brightest part of the subject and turned directly facing the brightest light source in taking the "solio time." Care should be taken that a coin be over the hole in the cover at the instant that it is placed down over the solio strip so that no light will fall on the solio through the hole except during the actual time that is purposely given by the worker. The system includes the following method of counting time with practical exactness:—To count any number of seconds say: Naught—one—half—and—one; one—half—and—two; one—half—and—three, etc.

The word "naught" only serves to start the time going, and the succeeding "one—half—and—one" serves to mark the finish of each quarter-second as it occurs.

To count one second only: "Naught—one—half—and—one." For a half-second: "Naught—one—half." And for a quarter-second say at talking speed the one word "quar—ter." Every photo

aphic worker should be an adept in counting time, and the mastering of this system of counting by practising it along with the second hand of a watch, in order to cultivate the correct speed, will be a desirable accomplishment for the worker. In a certain intensity of light the standard solio tint is secured in eight seconds, it makes no difference whether that intensity is created by the hour of the day, the season of the year, or the latitude from the equator. Furthermore, it might be created by a local cloud, or by taking a position a few feet from the side of a common window or opening. If we state that the solio time of a light intensity is eight seconds, we state a physical truth in simple numerals. If the light was one-half as strong its solio time would be 16 seconds, and if it were four times as strong its solio time would be two seconds. The "solio time" of an actinic intensity, then, is a true expression of its working power.

Now in my system of exposure this solio time of a light intensity is for convenience taken as a basic exposure, and with a certain emulsion and kind of subject the diaphragm is found that will result in the correct creation of the latent image when that solio time is given as the exposure. The simple statement of this diaphragm after each particular kind of subject (made larger or smaller for emulsions of slower or faster speed) gives what for convenience had best be termed a "solio diaphragm" of that subject for that emulsion. The subject table itself accounts for the characteristics of subject, colour, contrast, etc., while the diaphragm opposite that subject in the table accounts for the different speed of emulsions. The system is fully explained by the following simple sentence: "The solio time of the light at the brightest part of the subject is the exposure with the solio diaphragm of the subject as seen in the table." Now if the plate and film manufacturers will print this simple table which follows, and place in each box of plates and each roll of films that are placed on the market, anyone may open the package and with a strip of solio paper and a note-book with a hole in the cover, find the solio time of the light which abounds at the brightest part of the subject, and could see opposite the subject that is being photographed, the exact diaphragm with which that solio time would be the correct exposure.

I have not found a child of eight years of age who did not grasp the full meaning of the solio time of the light at once and with the greatest delight. They begin to think in the solio time of the light, recognising intuitively that a weak light will work slower than a strong one. The solio time of the light on a clear day with the sun fifty or more degrees from the horizon is practically one-eighth of a second, and may be used at that time without measurement. This is practically true from that height up to the zenith. This being true, it becomes easily possible to measure the light out of doors on bright days as well as in slower lights. Another benefit of this simple system is that it helps to create a universal photographic vocabulary. If some worker in Norway states that on taking a certain view the solio time was one minute, the mind immediately and fully grasps the exact truth. The fact that the Norway condition was created by the distance from the equator, the season of the year, and the time of day is entirely irrelevant to the subject. We might as well try to express the weight of things by taking the separate factors of length, breadth, and thickness, and that of specific gravity, and combining them.

A certain length might be called one, a certain breadth one, and a certain thickness one. Then a certain specific gravity might be called one, and when all the factors for any certain body were multiplied together some kind of an idea of weight might be obtained by mentally comparing it with other bodies. But if we have at all a simple unit of gravitation, why not balance the body on the scales and get its weight in those simple units instead of going around the proverbial bush and

confusing the world with useless mystery, as has too long been done in the practice of photography? The second, in which the solio time and all time is measured, is the only unit that is uniform throughout the world, and the measure, the strip of solio paper, is the most ideal measure of all the forces.

To measure gravitation we need scales, for volume a measure, for temperature a thermometer, for linear distance a rule or tape, etc. But for the standard tint we need but a thin slip of paper, many of which may be carried between the leaves of a book and which are almost without cost to the user. As to the counting of time, the mind is aided by the natural sense of rhythm which is the basis of time in music. This rhythm suggests the optimal system of counting, as the mind can best think in beats, and half and quarter beats, etc. (Aside from the subdivision of a beat by three as in waltz time.) For this reason it is logical to divide the second into the half, quarter, eighth, sixteenth, etc., in thinking of time. This is logical also for the reason that the diaphragms of the lens also increase and decrease in rapidity in the same ratio, by doubling and halving the time necessary for them to do a certain amount of labour, or by doubling and halving their area.

It would be well if the shutter manufacturers discarded the automatic exposures of $\frac{1}{2}$ of a second and slower, and allowed these times to be given by the mind and hand alone. They could then discard the unstable valve or "plunger" system of shutter construction and give us with simple and reliable springs the speeds of $\frac{1}{2}$ of a second and faster in the following scale as far as they could go: $\frac{1}{2}$, 1-16, 1-32, 1-64, 1-128, 1-256, 1-512, 1-1024, 1-2048. The last three or four intervals could only be given by the focal plane shutters, which should also give the intermediate speeds, for reasons of motion in the class of work which they are designed to do. This plan is simply to provide for the actual exposures that each diaphragm would demand when one exposure is known with a certain diaphragm and is too evidently useful to require defending. The only wonder is that the shutter makers have not seen this simple need and supplied it ere this.

The following table is for the Eastman film which I use in my own work. In using the table simply remember that the solio time of the light is the exposure with the diaphragm mentioned after the subject that is to be photographed. By reason of the great latitude of all photographic emulsions it is useless to make the solio time of the light any other than one of the following scale of exposures: $\frac{1}{2}$ second (the solio time with the sun high in the heavens on a clear day), $\frac{1}{4}$, $\frac{1}{2}$, 1, 2, 4, 8, 16, 32; 1 minute, 2, 4, 8, etc.

FRANK MORRIS STEADMAN.

AMERICAN NOTES AND NEWS.

An interesting exhibition of about 700 incandescent electric lamps, including the first experimental lamps made by Mr. Edison, is about to take place at the St. Louis Exposition. The collection is stated to be complete and unique, and to include a specimen of every kind of filament lamp ever made in Europe or America.

JACOB JEFFERSON FALK, youngest of the three photographers who have gained fame under their incorporated name of "Falk," died June 29 at a private hospital in this city from heart disease, complicated with other ailments. He was forty-six years old and lived in apartments adjoining his studio, in the top floor of the Waldorf-Astoria. Attacked seriously four weeks ago by the disease from which he had been a sufferer for several years, Mr. Falk was removed to a hospital and the gallery left in charge of his assistants. Funeral services were held July 1st in the Waldorf-Astoria.

In Chicago, on June 27, was held a meeting of professional photographers in sympathy with a movement to advance the financial interests of the profession. To attain this end it was agreed to organise the Photographers' Association of North America, whose work it would be to grant diplomas of efficiency to photographers in business, and certificates of ability to employees. A plan was also agreed upon for the establishment of an apprenticeship system, so as to insure a sufficient supply of really good workmen, and to discourage individuals from entering photography who did not possess the natural aptitude for the calling. The president is Mr. George G. Holloway, Terre Haute, Indiana, and the secretary is Mr. Dundas Todd, 908, Security Building, Chicago.

THE Bausch and Lomb Optical Company, Rochester, New York, has just placed on the market the new Zeiss lens—Tessar F.6.3. According to the business arrangements between this large American company and the firm of Carl Zeiss of Jena, the Rochester factory is now turning out this new objective in large quantities after the original formula of the inventor, Dr. P. Rudolph, and employing the new Jena glass recently discovered and now manufactured especially for the Tessar series. Bausch and Lomb, having completed the arrangements necessary for the production of this new lens, have announced their ability to give immediate attention to all orders. Literature descriptive of Tessar may be had from photo dealers throughout the country or upon request from the company's office at Rochester, or the various branch offices.

CERIC SULPHATE AS A REDUCER.—It will sometimes happen, despite all precautions, that the high-lights will become too dense before the shadows are developed in the negative. Carry the development as far as it will go is the method of Malcolm Dean Miller, of the Harvard Camera Club. Then to rectify it has the advantage over per-sulphate of ammonia of not needing a secondary treatment with sodium sulphite solution to stop the reduction, and, like per-sulphate, attacks only the denser deposits unless the action is greatly prolonged. It can be used on the dry negative, which then requires only ten minutes' washing. Ceric sulphate (Merck), 1 ounce dissolved in distilled water, 20 ounces. A precipitate will form after the solution is complete. Add concentrated sulphuric acid $\frac{1}{2}$ ounce which reduces the excessive contrasts nothing is so good as ceric sulphate. It dissolves the precipitate. This reducer can be used until exhausted, which will occur only when it loses all its yellow colour.

THE Americans are speculating on the possibility of imitating the Germans in producing wood-spirit for industrial purposes.

An immense amount of wood is cut down every year in the States for conversion into charcoal for the iron foundries. But of late years, beside nearly every charcoal plant there has been raised a chemical plant, to rescue the wood-alcohol from New York and Pennsylvania eighty wood-alcohol and acetic acid plants exist, which supply the iron foundries with charcoal for the spirit and acetic acid as by-products—the alcoholic output amounting to a million and a half gallons a year. In Germany alcohol is so cheap that several foreign alcoholic motor are working. Whether this result will follow in America remains to be proved; but there is assuredly a future for wood-spirit, which only the other day was all lost in smoke. It is computed that now from 75 to 80 per cent of the tree, branches and all, is utilised for the up-to-date charcoal maker.

A PLATE BACKING.—One of my friends has been experimenting with the various mixtures recommended for the backing of plates, remarks Fayette J. Clute in "Camera Craft." He has spoiled a goodly number of holders and wasted a few dollars not to mention much time. He has finally settled on a mixture of lamp-black and gum-arabic. He measures it out with an old spoon; two of the lamp-black to one of the gum-arabic. He goes to the stationery store, and then adds enough water to make the desired consistency to work up nicely with an old knife-blade used as a spatula. When it is thoroughly mixed it is put into an old tin box-lid and allowed to harden in the cake. A wet rag is used to apply it to the plates, and the results I have seen it is certainly a most effective preventive of halation. It is the easiest thing in the world to rub in just before developing, and only the thinnest coating is required. Beware of any backing containing glycerin, as it will draw enough moisture from a damp atmosphere to ruin silver-containing plates so backed.

AMATEUR PHOTOGRAPHY AT ST. LOUIS.—The American dealers are now all getting rolls of films from their customers who are at St. Louis taking advantage of the free use of their cameras on the grounds of the Louisiana Purchase Exposition. All exposures are overtimed, in some cases so much so that it is impossible to secure good negatives from them. Our readers who contemplate using their cameras at the Fair should remember that white buildings require about one-fourth the exposure of ordinary street scenes. Another thing that should be remembered is the fact that a street scene hedged in by tall and closely arranged buildings of a more or less drab colour is an entirely different proposition from such street scenes as are at their disposal at the Exposition. Even time that one is accustomed to give to fairly open landscapes will be found too long, for the simple reason that green foliage is rather non-actinic and does not reflect light on neighbouring objects, while white buildings act much as does the white reflector the photographer draws up near his sitter in order to lighten up the shadow side of the face. Cut your exposures down at least one-half and you will be doing better work and have the thanks of the man who develops your films.

FITNESS FOR PUBLICATION.—At the present time East London publishers and photo-engravers are deep in argument and discussion over what makes a picture unfit for publication, says "Camera Craft." It seems that several photo-engraving houses that do designing have had cuts returned to them with a refusal to pay because some publisher had said they were "unfit for publication." The engravers were up in arms and said the cuts were no "worse" than those appearing constantly in the "home" journals. Now they are calling out loudly for some one to define the line between fitness and unfitness for publications. But such a line cannot be drawn. The photo-

graver must simply use his own judgment. It all depends where the picture is to be printed. A certain class of anatomical pictures are not indecent when printed in a medical journal. Photographs of corsets and underwear on a living model are all right in certain household publications (if they were not it would be a sad thing for the advertising business), but they are very objectionable in a daily newspaper. Artists' juries have only two tests that they follow when selecting pictures for exhibition. First they consider the "sense" of the picture. Is the idea it conveys fit for a decent mind? Then they make a fine distinction between nudity and nakedness. And, after all, what can a living can do more?

SEA-WATER.—A Kodak enthusiast who was crossing the ocean a few months ago found trouble in getting enough fresh water for use in operating his developing machine. To him a voyage without the pleasures of photography seemed tedious, and so he decided to take a chance on one roll with sea-water. Water direct from the briny deep was used for developer, for fixer, and for washing, with just a short final rinse in fresh water to remove the salt, and his negatives were perfect. He developed his remaining rolls in a similar manner with equal success, and told us with enthusiasm of his results. Further tests on the part of Kodak Limited have proved that the scheme is perfectly practical that sea-water may be safely used for all the processes provided only that the final rinsing is in clean fresh water. Mezzo-Tone was not on the market at the time the enthusiast experimented with sea-water in his developing machine. If it had been he would probably have discovered that it answers admirably for toning that paper. Very little fresh water need be used. The process is this: Print; place prints for ten minutes in sea-water, during which time they will clear and tone; fix in: Sea-water, 10 oz.; hyposulphite soda, 1 oz.; Solio hardener, 10 drops. Fix 15 minutes. Wash 14 changes of sea-water and then for five minutes each in three changes of fresh water.

The "Saturday Evening Post" relates an interesting story how the late President McKinley was photographed when once on a trip to New York: Mr. Shackleton, the author, was assigned to a newspaper to "get a story." He had with him his assistants, among others a photographer, and when the Presidential party took their way up the harbour the newspaper party followed in their chartered tug. The President shared the dislike many public men to the indiscreet snapshot, and quickly detected the photographer the minute he took his position; not, without experience of the ways of cameras, he smiled and held his ground when he realised that he stood with his face in a sharp shadow and his body in the bright open-air sunlight. The face would show a blank, he well knew. And so it did. The negative was perfect but for the face, and that was completely lost. But they are resourceful in newspaper offices. Such a lost picture was not to be lost. The photographer hunted up a black portrait of ten years back, made a transfer of the old features to the new shoulders, and when the paper was printed, there stood the President to the life! Nobody was more astonished than the President himself when he saw it. It is only fair to add that he was more than half pleased at the likeness. Mr. McKinley was frankly so. The tactful Mr. Cortelyou, then secretary to the President, was careful to let Mr. Shackleton know as much when he called. "She said," he repeated, "it was the best portrait the President has had in years. Why, he looked ten years younger!"

BLACK BACKGROUNDS.—The field of chiaroscuro has been so thoroughly covered in the photographic journals that there

seems little left to say. But a few words on the very black background occasionally used in portraiture will not be amiss. The most frequent criticism of that kind of background is that it is too dark and lacks gradation. But why should a part of a picture not lack gradation and not be dark, even black as night? It is certainly frequent enough in nature. Walk through the streets on a summer afternoon and study any open window in which perchance is sitting a girl dressed in white. If the illumination is at all right, the draperies and flesh will be brilliant and the interior of the room intensely black, and the combination of the two most beautiful. Why is it that so many photographers, when they try to imitate this effect, fail completely? It was one of the favourite schemes of the Florentines and Reynolds. How did they do it? Leonardo gives the hint. He tells you to pose your model within the doorway of a darkened room hung with dark draperies, and to illuminate the figure with sufficient light from the room in which you are painting. If you are not possessed of the proper accommodations, construct them for yourself with screens, etc. Now wherein will this effect differ from the one in which a piece of dark cloth is placed directly behind the head? That is easy to explain. Your sitter, being a little inside of the dark room, is receiving no reflected side light, and the parts of the head and figure as they round become rapidly darker until at their edges they are almost black and sink softly into the background. Whereas a head ordinarily placed against black will merely silhouette, and further, the negative should be developed and printed to obtain as black a black as is possible, for coal black possesses a quality of intensity and vigour which the mind associates with no grey.—J. C. ABEL, in "The Photographer."

THE USE AND CARE OF PHOTOGRAPHIC LENSES.*

Of all the special phases with which we come in contact in dealing with the subject of Photographic Lenses, their use and care are the most simple, and, at the same time probably the most interesting and important. We will first consider the Use of the Lens. My motto is: "First—the lens. Next—the man behind the lens." If I should ask you to give a definition of the word "lens" I wonder how many could reply. I will not ask for a definition because I myself may be unable to tell you what constitutes a lens. I will, however, give you a definition which I trust will convey to you what constitutes a lens as I understand it. A lens is an instrument with at least one curved face and maybe composed of any substance through which light may be transmitted. You will easily see by this definition that the number of different kinds of lenses may be infinite. They may be composed of glass, liquid gases or any transparent substance. But we are to consider only the photographic lens, and I think best to consider only those in most common use. They are the portrait lens, the rapid rectilinear, the wide angle rectilinear, the single combination landscape, and the condensing lens. To simplify our deliberations we will consider just the point in optics.

First Light always travels in straight lines, unless acted upon by some substance through which it passes, or against which it strikes, and is neither refracted (bent out of its course) or is reflected in a different direction from its original course and after refraction or reflection it again travels on in a straight line for ever, or until it is absorbed by some substance against it again strikes or through which it passes.

Second:—Points reflect light in all directions.

Third:—Objects are composed of an infinite number of points and each point reflects its own light and the image of an object is formed on the focussing screen or the sensitive plate by the light from each point passing through the lens separately and individually and not the object as a whole. Hence, a point, say at the top of a building, reflects some of its rays downward which pass through the lens to the top of the plate, and hence the image always appears upside down on the screen. This is true of light passing through

* A lecture delivered before the Photographic Association of Wales in 1902.

a pin-hole made in a piece of opaque paper used as the front board of your camera. The primary object of the use of a lens in making photographs is to admit the passage of a very large pencil of light and bring all the rays reflected from any one point to a focus (or a point) on the plate. By this we can readily understand that the larger the aperture of a lens of any given focal length the more light will be admitted and, therefore, the faster the working of the lens.

The essential difference between a portrait lens and a rapid rectilinear is in the amount of light that each will admit, or their angular aperture. A portrait lens having a very large opening, or more properly speaking, a greater angular aperture, admits a greater angle of the divergent rays of light from any point and therefore easily produces that much sought for roundness of image not possible to be obtained with a rapid rectilinear lens or one of small angular aperture. Hence, the wise photographer will always select a good lens, having a very large aperture in proportion to its focal length. But we shall see, that as we increase the angular aperture, the corresponding depth of focus (that is, the satisfactory production of images of objects at varying distances from the lens) decreases. For this reason it is best to select a lens of smaller aperture for, say, landscape work and which, also by reason of its smaller diameter is generally constructed along lines which admit of greater depth of focus. These principles, I think, make it very plain why a portrait lens is not good for landscape work and vice versa, why a rapid rectilinear or landscape lens is not so good for portrait work.

It is conceded by all strictly landscape photographers that a single combination landscape lens produces the most brilliant image. This is due to the fact that all the lenses being cemented together, there are fewer reflecting surfaces to diffuse the light falling upon the sensitive plate. But while this form of lens has its advantages, it also has its disadvantages. When one of these lenses is used for photographing architectural subjects it will be seen that the straight lines of a building especially when the lens is required to include a medium wide angle, will be somewhat curved. This is due to the fact that the diaphragm being placed at a certain distance away from the lens, the pencils of light meeting the lens at an angle from its optical axis, cross one another passing through the lens near its edge. The spherical aberration found in all lenses causing a straight line in the object, to be slightly curved in the image produced.

A wide angle rectilinear lens is very similar to a rapid rectilinear. The essential difference being the lenses are mounted relatively close together. It will be easily seen that if two lenses be made each one inch in diameter and one system be mounted one inch apart the other mounted two inches apart, the system one inch apart will admit of a much wider angle of light than the one mounted two inches apart. Of course, when a very wide angle is to be included it is necessary to construct the lens with a very different system of curvatures. This is necessary from the fact that when the front and back combinations of a lens are brought closer together the curvature of the field is increased, and this accounts for the fact also that it is always necessary to use a smaller stop in a wide angle lens than in a rectilinear one.

Many photographers ask why it is necessary to employ the use of a condensing lens in order to make copies, enlargements, etc., from negatives. The reason is this: when an artificial light is placed back of a negative its rays pass in a direct line through the negative, then through the lens at its optical axis to the plate. It is only reasonable to conclude that rays which do not pass direct, and at best can only be reflected through the lens, will not be as strong as the direct ones and hence a greater illumination in the centre even when a ground glass be used between for diffusion. A condensing lens gathers all the rays at whatever angle it may be constructed for and bends them, bringing them to a focus at some point within the projecting lens used for producing an image of the plate to be copied, and hence each ray of light passing through it, is, as direct from the source of illumination, and the result—an evenly illuminated screen or image.

Now I will call attention to this new invention in photographic lenses—perhaps I should apologise at this point for mentioning this invention at this place, because I happen to be the inventor of this new lens.

When the image of some suitable object, say the flat front of a building or a standing figure in your operating room be projected on to the ground glass screen by means of the best portrait lens, in fact, the best rapid rectilinear lens at full aperture, the marginal parts of the image, as you know, appear indistinct, out of focus when the centre is sharply focussed, and the image is sharply focussed, the centre will be blurred and indistinct. This shows that the plane of the image is curved. This difficulty is due to the fact that the lens has been corrected for smaller diaphragm, and when a sharp image from the centre the edges of the plate is desired it is necessary to stop the lens down to produce it. We have observed, as in the case of the wide angle lens, if the tube carrying the lenses be lengthened, the field becomes flatter and flatter as we do until a point is reached where the field of the image is perfectly flat and clearly defined all over the plate and hence the face, hands, and feet of a standing figure will all be sharp and likewise the flat front of a building, a copy of a photograph, maps, drawings, etc. We will find, however, that if it be necessary to stop the lens down for depth of focus the image will not be so good with the lengthened tube as if it be shorter. I have therefore provided my lenses with a double sliding tube which is operated by a ring and a knob similar to an iris diaphragm, by means of which the tube can be instantly lengthened or shortened at the will of the operator to suit his particular need. It is a very simple matter to learn to use the device, and you will be surprised how much you can accomplish by its use that will be impossible without it. I will only just a few more of the many points of advantage. When it is desired to photograph a figure in a sitting position, as you well know the hands and knees are closer to the camera than the face. It is always necessary to draw the focussing screen farther away from the lens to obtain a focus of a near object than for one of a great distance. Hence, when the knees and hands are in focus the face is out and vice versa. For this reason you resort to the swing back swinging that part of the screen receiving the image of the hands and knees farther away from the lens in order to obtain a sharp focus. Now the image of the hands and knees, which are already too large, are made larger still because of the greater distance of the screen, and the result is a very distorted image. With the adjusting device it is only necessary to turn the ring a short distance, shortening the lens tube, making the field more round, and the hands and knees come to a focus on the screen without the necessity of swinging it away from the lens and the resultant image is not distorted. One more point and I will quit bothering you with the use of the lens.

It is admitted by all lens makers that a lens must be correctly to one certain diaphragm. This being the case, the lens is certainly working at a slight disadvantage. With the adjusting device the tube may be lengthened or shortened as you use a larger or smaller diaphragm and the best possible correction be maintained at your own will throughout the entire system of diaphragms. The adjustment is supplied with a graduated scale with the usual normal setting of the lens marked, and should you be in too great a rush with your work to stop to adjust it for some subjects, it can remain and your lens used same as any lens in rigid mounting. The device applies equally well with lenses for any work, and a rapid rectilinear lens may be transformed into a wide angle lens for large plates and a regular wide angle rectilinear can be used as an extreme wide angle, by simply turning the ring bringing the lenses closer together.

Yet another very important point comes to my mind and I will name it. The so-called chemical effect of your plate you will find to be very much improved when the proper adjustment is used for the diaphragm you employ. I will give you my rule for the use of diaphragms or stops as they are commonly called.

Rule: Always use the largest diaphragm you can that will produce the character of image you want. Never stop a lens down until the image appears satisfactory and then say, "Well, I must have a sharp picture, so I'll just use one size smaller stop and be sure it." Too small a stop destroys roundness of image and consequently stereoscopic effect.

A few words only is necessary as to the care of a lens. In the first place your lens should always be covered when not in use, as to prevent, as far as possible, any dust from falling on to the glasses. Your lens should be kept in a room where it will not be

subject to any great and sudden changes of temperature and where the atmosphere is fairly dry. It should be carefully cleaned, especially if new, at least once a week. Most of us would feel very sorry if we should accidentally make a small scratch on our lens. I want to say that a large amount of dust on a lens does infinitely more injury to the picture than a scratch, even if of considerable size, but we do not want either and the best thing to do is to keep the lens clean and be careful in cleaning it. Hold your lens up so as to be able to lightly dust it from the under side with a camel's hair brush or a soft chamois skin used only for this purpose. Then wipe the surface gently, if necessary, with another chamois that has been washed free from oil and used only for the purpose of wiping your lens. A piece of silk tissue paper, or a piece of soft cambric or a clean handkerchief that has been washed a few times are also good. In this climate the lens should be taken apart and all the inner surfaces wiped as they collect a scum which destroys the brilliancy of the image and renders the action of the lens much slower. In fact, the every precaution to make the required work of your lens easy and effective. You will not then have occasion to expatiate away the many difficulties which meet most of our brother photographers—the picture is too flat or too harsh a contrast, shadows too black, hands too large, feet out of focus, "My nose does not look like that," "My mouth isn't straight like that," etc., etc. Every observing operator will tell you that there is always two sides to every one's character—the good and the bad side. Always observe to photograph your subject when he or she is in a pleasing condition of mind, being careful to adjust your lens, your camera and your focussing screen so as not to distort the lines showing the character, and you will have very few complaints from your patrons.

L. F. DEARDOFF.

RESULT OF THE KODAK £1,000 AMATEUR PHOTOGRAPHIC COMPETITION.

N. C. FILM COMPETITION.—CLASS "A."

First prize, Mrs. R. Dunlop; 2nd prize, W. Scott Elliot, jun.; 3rd prize, Miss Laura Adams Armer; 4th, Hedwig Ledermann; 5th, Miss G. F. Nash; 6th, James Dunlop; 7th, Mrs. Helen W. Corke; 8th, John S. Neary; 9th, H. A. Briscoe Harrison; 10th, D. J. Cartwright; 11th, William Deeley; 12th, Geo. Adamson; 13th, C. White; 14th, Thos. A. Morgan; 15th, Frank Salisbury; 16th, G. W. Blyth; 17th, Miss M. Holmes; 18th, A. Vigar; 19th, Mrs. Cleasby; 20th, Geo. F. Fisher; 21st, J. Burns; 22nd, Albert H. Joberg; 23rd, Miss Nellie Coutant; 24th, William C. Motteram; 25th, Barter Johns; 26th, C. Azuhner; 27th, Gaston Lecouvey; 28th, Luigi Chessi; 29th, E. Hoppe; 30th, Miss M. Masters; 31st, C. R. Ritchie; 32nd, Miss H. B. Cole; 33rd, Robt. G. Klotz; 34th, John Regan; 35th, M. Leduc; 36th, Patrick Bataille; 37th, Eldred M. Leays; 38th, Victor Stouffs; 39th, Mlle. Emilie Tremblay; 40th, Miss Agnes L. Brown; 41st, Louis J. Christie; 42nd, Henry S. Whitney; 43rd, Madame Albert Huguet; 44th, Miss M. E. Brockbank; 45th, H. A. Rothrock; 46th, Julius Stadler; 47th, Ferry Croner; 48th, Miss Dorothy M. Platt; 49th, W. Frahm; 50th, H. B. Conyers; 51st, Dr. A. R. Benedick; 52nd, Miss C. Joan Bacon; 53rd, E. Makaroff; 54th, Mlle. Ethyl Amelye Weisel; 55th, Chas. Siegler; 56th, W. Mair Bishop; 57th, U. K. Brocklehurst; 58th, A. A. Johnstone; 59th, Frau Hofr Jettel; 60th, Hon. Edith St. Jeager; 61st, Miss Mary L. A. Davie; 62nd, Miss E. M. Craig; and 63rd, Miss Borrowman.

N. C. FILM COMPETITION.—CLASS "B."

First prize, John Dolman; 2nd prize, Emile Frechon; 3rd prize, W. A. Casson; 4th, Walter Zimmerman; 5th, Miss Kate Smith; 6th, Miss Elsie Ross; 7th, M. M. Lailler; 8th, Rev. A. M. Walters; 9th, Mrs. Nancy Ford Cones; 10th, E. Alix; 11th, F. W. Beken; 12th, H. M. Tapp; 13th, Edgar J. Parker; 14th, L. Komarnicki; 15th, Patrick Bataille; 16th, Henry Neistle; 17th, Mlle. Lamire; 18th, Miss M. Tavernor; 19th, Mrs. Turnbull; 20th, G. F. Jackman; 21st, E. W. Enfield; 22nd, H. Mortimer Lamb; 23rd, Thos. A. Morgan; 24th, Geo. L. Beam; 25th, Laurence Osgood Macomber; 26th, Miss Florence Howland; 27th, William Leon Graves; 28th, Edgar R. Bull; 29th, E. J. Appleby; 30th, Josephine E. Corby; 31st, J. F. Revilloid; 32nd, M. Schneider; 33rd, A. H. Robinson; 34th, G. Banchart; 35th, H. C. Card, jun.; 36th, Chas. M. Carter;

37th, C. F. Allsup, R.N.; 38th, Leonard Marshall; 39th, Mrs. Pollock; 40th, W. Maclean; 41st, Lieut. F. M. Bailey; 42nd, Mrs. Cleasby; 43rd, H. B. Conyers; 44th, Harry Bruce Sutton; 45th, Dr. H. Bachmann; 46th, Frank Salisbury; 47th, Alex. N. Wishaw; 48th, T. Taylor; 49th, Mrs. S. C. Comstock; 50th, Miss Grace E. Mounts; 51st, Miss Mackay; 52nd, Miss Battiscombe; 53rd, Joseph K. Bridgeman; 54th, John Hayward; 55th, Mrs. Helen W. Cooke; 56th, W. Scott Elliot, jun.; 57th, Stanley J. Milner; 58th, Miss Mary C. Eames; 59th, John S. Neary; 60th, Iskandar Makarius; 61st, G. Thurin; 62nd, E. Lepeinteur; and 63rd, Eugene Lorimey.

N. C. FILM COMPETITION.—CLASS "C."

First prize, P. S. Greig and E. B. Vignoles; 2nd prize, A. S. Howard; 3rd prize, Miss C. Joan Bacon; 4th, Frank E. Beresford; 5th, Mrs. Godfrey; 6th, Laurence Ridges; 7th, Miss Laura Adams Armer; 8th, Miss Swinton Browne; 9th, Mrs. L. R. Graham; 10th, Miss Nellie Coutant; 11th, H. W. Raisin; 12th, Miss Grizel M. Turnbull; 13th, Thomas A. Morgan; 14th, Rev. A. M. Walters; 15th, Miss Emmie Cochrane; 16th, John Dunlop; 17th, L. Lloyd; 18th, Mrs. Bertram Goddard; 19th, Gustave Moeller; 20th, Miss Esme Cunningham; 21st, John Schuler; 22nd, H. B. Conyers; 23rd, Geo. Hartley; 24th, Ernest G. Elbourne; 25th, Hannes Pyska; 26th, Miss Helen Pollock; 27th, Miss Lucy Guitard; 28th, Miss Dorothy A. Dobree; 29th, Chas. H. Loeber; 30th, J. G. Dickinson; 31st, Thos. Norton; 32nd, Miss Elizabeth Hill; 33rd, Miss C. Stewart; 34th, David C. Pendrigh; 35th, Miss Edith M. Laurence; 36th, Miss F. Baggs; 37th, L. Carter; 38th, Miss Laura Brocklebank; 39th, Edgar Steinmetz; 40th, Mrs. A. J. West; 41st, Miss Cooke; 42nd, Miss Kathleen Hayes; and 43rd, Miss E. Halsey.

KODOID PLATE.—CLASS "A."

First prize, Mrs. G. A. Barton; 2nd prize, W. Fisher Ward; 3rd prize, Miss Laura Adams Armer; 4th, Thos. F. Brogden; 5th, Archd. Richmond; 6th, E. Calland; 7th, Emil Frechon; 8th, Thomas A. Morgan; 9th, Miss Agnes Tomlinson; 10th, H. Mortimer-Lamb; 11th, P. S. Greig and E. B. Vignoles; 12th, Frank W. Gregg; 13th, W. Fotheringham; 14th, A. Morrison; 15th, Walter Zimmerman; 16th, S. R. Carter; 17th, Will A. Cadby; 18th, Horace E. Hopkins; 19th, James D. Ross; 20th, M. Mamitsch; 21st, Wm. M'Lean; 22nd, P. R. Denham; 23rd, Arthur Langridge; 24th, R. Burrow; 25th, A. Bedding; 26th, F. Schneider; 27th, Mrs. R. Dunlop; 28th, Chas. E. Wallace; 29th, J. R. Batey; 30th, Miss J. L. Griffiths; 31st, J. Peat Millar, jun.; 32nd, Harry C. Rubincam; 33rd, Rev. Henry W. Dick; 34th, Chas. J. Reade; 35th, Eugen Boveraux; 36th, Mrs. M. P. Durn; 37th, A. H. Avery; 38th, Miss Elsie Ross; 39th, Dr. O'Connell; 40th, W. Clifford Warner; 41st, F. Napier Sutton; 42nd, P. Coles; 43rd, J. C. Warburg; 44th, Chas. S. Price; 45th, W. H. Edgar; 46th, R. Romans; 47th, Gerhard Steylen; 48th, Mrs. E. D. Girdlestone; 49th, Dr. Albert R. Benedick; 50th, Fred. T. Sheret; 51st, A. W. Cooper; 52nd, H. A. Briscoe-Harrison; 53rd, Robt. Burnie; 54th, W. H. Haler; 55th, F. E. Huson; 56th, Harold A. Ray; 57th, G. A. S. Orlebar; 58th, Miss Chichester; 59th, E. W. Burch; 60th, H. Wild; 61st, O. Thornycroft; 62nd, Frank Wilkey; 63rd, T. Bletcher; 64th, Rev. E. S. Palmer; 65th, J. C. Richards; 66th, R. T. Christopher; 67th, W. S. Crocket; 68th, A. Cohen; 69th, W. Cunningham; 70th, F. A. Joyner; 71st, T. P. Rogers; 72nd, F. Chapman; 73rd, Will E. Gladwish; 74th, Sumner W. Matteson; and 75th, Mrs. L. R. Graham.

KODOID PLATES.—CLASS "B."

First prize, Andre Callier; 2nd prize, D. J. Cartwright; 3rd prize, H. Light; 4th, Fredk. H. Evans; 11th, F. Napier Sutton; 12th, John W. Martin; 13th, F. G. Mudge; 20th, H. Bazin; 21st, Louis R. Murray; 22nd, J. Hesford; and 24th, Rev. Henry W. Dick. In this class the judges withheld some of the prizes and awarded in other sections.

N. C. COMPETITION (ENLARGEMENTS).—CLASS "D."

First prize, Alfred Miller; 2nd prize, Miss Laura Adams Armer; 3rd prize, Rev. A. M. Walters; 4th, A. Gibory; 5th, Mrs. G. A. Barton; 6th, Walter J. Clutterback; 7th, H. A. Briscoe-Harrison; 8th, Wm. C. Motteram; 9th, A. H. Robinson; 10th, Will A. Cadby; 11th, C. D. Paton; 12th, Miss Kate Smith; 13th, Walter Zimmerman; 14th, Annie W. Brigman; 15th, Henry Neistle; 16th, Herbert Bairstow; 17th, H. B. Conyers; 18th, P. Vandenput; 19th, C. J. Reade; 20th, George L. Beam; 21st, Thomas A. Morgan;

22nd, Hon. Constance Kerr; 23rd, W. A. J. Hensler; 24th, Miss M. T. Adams; 25th, Mrs. Henry; 26th, F. N. Sutton; 27th, Laurence Osgood McComber; 28th, J. R. Redfearn; 29th, Madame Albert Regad; 30th, M. Urosa; 31st, E. A. Price; 32nd, G. B. Griffiths; 33rd, R. L. Whitworth; 34th, William Meilroy; 35th, Mrs. Myra A. Wiggins; 36th, Miss A. B. Cole; 37th, T. Ernest Waltham; 38th, Harold Hood; 39th, Frank Pinder; and 40th, A. Tundley.

DEVELOPING MACHINE.—CLASS "A."

First prize, H. Oswald Isaac; 2nd prize, Miss Nellie Coutant; 3rd prize, Leonard Marshall; 4th, F. Napier Sutton; 5th, Madame Henri Fourme; 6th, Madame C. Poisson; 7th, E. V. Duckworth; 8th, E. Jepson; 9th, Maurice C. Vgoyan; 10th, J. C. B. Appel; 11th, L. H. Harrop.

DEVELOPING MACHINE.—CLASS "B."

First prize, Miss Stone; 2nd prize, Miss N. Coutant; 3rd prize, Mlle. Severine Gabelle; 4th, Paul Massia; 5th, Miss A. Mitchell; 6th, H. E. Wrotterley; 7th, Mrs. Sutherland; 8th, Harry R. Cate; 9th, Jas. Walker; 10th, Mrs. S. C. Comstock; 11th, Mrs. L. R. Graham; 12th, E. J. Duncombe; 13th, Miss L. M. Shortt; 14th, E. B. Owen; 15th, Miss Constance de Striger; 16th, Mrs. E. Bromley; 17th, T. Ernest Waltham; 18th, Ernest Abrahams; 19th, Miss Comley; 20th, J. A. Young; and 21st, Madame Henri Fourme. In both sections of this competition the judges withheld prizes and awarded in other classes.

SPECIAL PRIZES.

Will Cadby, Mrs. Cadby, T. G. Cochrane, Herbert J. Hughes, Madame Albert Huguet, Miss Lilian S. Owen, Miss Louise V. Hitchcock, G. Carpentier, H. Jackson, S. C. Comstock, Mrs. S. C. Comstock, W. Robertson, Josef Brunner, A. E. Littler, Giovanni Aita, Henry Troth, William C. Motteram, Josef Edler von Douhauser, Herbert C. Hughes, Brian A. Reeves, Laurence G. Reid, Ernest H. Hooper, Miss Stocks, Ernst Budina, H. Bazin, L'Abbe Larivet, Miss Edith K. Brown, G. A. Fowkes, Amtsrichter Raykowski, C. Blanchet, A. Waterall, Miss Bruere, Frank H. Stevens, John Hayward, T. S. Boudoin, C. S. Sargisson, Miss Margaret Smith, Fred W. Levett, Geo. Heys-Jones, Lady Helen Lacey, M. M. Hodgson, L. C. Burchardt, H. C. Rubincam, Miss M. Nelson, F. Cowley, Valentine Lora, A. Haton, M. Schablin, Miss H. B. Cole, G. F. Fisher, Eugene Francois, and Miss Jean L. Clemens.

THE INFLUENCE OF DILUTION OF THE DEVELOPER UPON THE CHARACTER OF THE PICTURE.

To become acquainted with the advantages of diluted developer and the nature of its action, tests should first be made with the development of three uniformly exposed sensitometer plates, one with normal developer, and the other two with developers of different dilution. The different character that can be observed on these pictures, sharpens the judgment about the proper way to obtain a good negative.

To make such a test, expose three small plates, cut from a highly sensitive dry plate, under a scale sensitometer from one to sixteen tissue-paper layers, at equal time with the normal light quantity of 120 meter-candles seconds. Have three developing trays in readiness. The first contains normal developer, 1:30; the second, 1:50; and the third, 1:300. In the first, the developer is, therefore, of a normal composition; the second is diluted five times, and the third has a ten-times' dilution. Place now the exposed plates into the trays, and observe the time at which the picture appears. In No. 1 the picture comes in 40 seconds, and is fully developed in four minutes; that is, the weakest light impressions, 13 to 16, are just visible. Picture No. 2 appears in 4 minutes, and the plate has to be left in the bath for 24 minutes, to be able to read the figures 13 to 16. Upon plate No. 3 the picture appears in 12 minutes, and requires 84 minutes for the development of the figures 13 to 16. The time of development is, therefore, not proportional to the dilution, as a five-times' dilution does not require five times but six times the time, and the ten-times' dilution not ten times but twenty-one times the time. If the plates are observed from the glass side, it will be seen that No. 1 has a thorough development at the strongest exposed

parts, while No. 2 is weaker, and No. 3 has no thorough development. This explains easily that after fixing the gradation and therewith the character of the pictures is entirely different. No. 1 shows the 1 to 4 well covered and sharply contrasting towards 13 to 16. No. 2 the covering from 1 to 4 is weaker, and with it the contrast towards 13 to 16. No. 3 shows a still weaker covering in the 1 to 4, and still less contrast towards 13 to 16. Expressed in plain language, the negatives become softer with increasing dilution, the result proves the excellence of a diluted developer for undeveloped plates, which, in concentrated developers, would give hard negatives. In such cases very delicate negatives of moderate covering are obtained by diluted development, but they contain tones in correct proportion, and can be changed by intensification into harmonic, well-printing negatives. Further advantages of a diluted developer are, a greater clearness of the picture and a reduction of the light halos, which are only strong when the plate has sufficient thorough development. Each plate of doubtful exposure should be put first in a ten-times' diluted developer, and the time should be observed at which the picture appears. Under the conditions of the above case, a normal exposure would be made when the picture commences to become visible in 12 minutes. If observation were to show a time of only 6 minutes, it would look like an over-exposure, and to save the negative the plate would have to be finished with a very strong developer, with a good addition of bromide of potassium. If the picture would not appear before 12 minutes in the diluted developer, under exposure would be the case, and the plate should be left in the diluted developer until the most delicate details were visible, and the negative can then be intensified.—JOHN GAEDT. Translated by Henry Dietrich.

LIGHTING.

For the past forty or more years various ideas have been advanced by various workers for the lighting of the face as we see it under the light, and personally I have not the slightest doubt but that all claims made have been "founded on fact," so to speak. In other words, every worker is a "law unto himself," and manipulates the light to suit himself. But there can be no question that there must be a right and a wrong way of lighting. Now the next question for consideration would naturally be: What is the right and what is the wrong way? The answers to these two questions are so obscure and hard to arrive at that the average worker almost hesitates to go any further in his investigations. One great, and perhaps the greatest reason for his hesitation lies in the fact that we, as photographers, cannot, with any degree of positiveness, point to a particular name or person as being a recognised authority. We perhaps the reason may be found in the fact that we are young men, years as a profession, many of our earliest followers yet living, and it is a historical fact that the benefit of one's knowledge and efforts are seldom reaped until after one has passed over the "great divide." With the artist, or the follower of Rembrandt, Rubens, Turner, Murillo, Michael Angelo, and perhaps scores of others, it is different. For ages past their ideas, and in many instances their advice and their instructions, have been handed down to their successors until it has almost become a sacred matter to those receiving them. Yet as photographers, dealers in "light and shade," have and are now "worshippers afar off," trying with our meagre possibilities to give a little instruction from these selected few. It is an old and tiresome saying that we are hampered by not having "colour" to aid us in our endeavours. This saying, like most old sayings, is true, and we must sooner or later realise it. As soon as we have reached this station in our professional career the next consideration is, how am I to make work that will be classed as artistic? To this question there can be but one answer, and that is, by so controlling your lights as to secure artistic effects in black and white, the only means at our disposal for producing pictures up to the present time.

In my personal experience under the light, which has extended over twenty-one years, and in handling all classes of subjects have found that there is one main consideration to be taken into account in producing artistic work, and that is the direction from which the light falls on the subject. There are other considerations of a minor importance which will doubtless enter into the light

of the face, but they are in no wise to be compared to this one of direction."

It has been my privilege within the past few years to attend a large majority of the State and national conventions, where I have heard the various claims made, and seen the demonstrators work the light in their own way, and I have found that in all cases their first thought was for the direction of the light as it fell on the subject.

One man would claim that he used as large a source of light as he could possibly get; in other words, he used no curtains of any description on his light. But I noticed when he demonstrated his method of work he would have his subject posed at least as far from the side light as his top light would measure upward from where it joined with the side light. For example: If we are using a light, the top light of which measures twelve feet from the side light up to its highest point, and we pose the subject twelve feet into the room, measuring from the lower end of the side light, all that will then be necessary is to lower the curtain (if curtains are used) on the side light just enough (no more) to secure a catch light in the eye (or speck, as the public calls it); this light is thus obtained, provided, of course, that the head has not been turned so far away from the light that no light at all strikes the shadow side of the face. In this connection I would say, that as soon as there appears soft light on the shadow cheek, which will be due to the face being turned far enough to the light to catch it, if the light from the side is low enough the catch light will appear. If no curtains are used on the light there will be no question on this point, as the catch light will show itself just at the instant the face is turned far enough to the light to show the soft light on the shadow cheek. Now, someone (or more, perhaps) will think, "Yes, this may be good under a double slant light, but I have no single slant; what all I do?" Do just as that brother did who was using the double light. Have a certain portion of your light top light, and the other portion will be side light, and for all practical purposes it will be and to work the same. If, for example, the upper half of your light is ten feet, the subject should be faced ten feet into the room from the light.

At this stage of the game we run up against another point of lighting that has often been mistaken for a principle of lighting, and that is, the question of the strength of the light as it rests on the subject. That is, whether it be strong, bordering on contrast, or soft or delicate. This, to my mind, is not a principle, but merely personal preference, and is to be determined by each operator for himself. Over and over we see pictures by men of national reputation, one making strong, bold lighting, the other soft, delicate, and full of detail, but upon a close examination we find the light falling on the subject from the same direction, *viz.*, half way from the highest point in the opening of the light and its lowest point, or, in other words, it is known to the average worker, an angle of forty-five degrees. As to the size of the opening, that has, in my opinion, nothing to do with the resulting negative other than the consideration of whether the light shall be a negative strong in contrast or one of soft, delicate quality—the smaller the source of light, the more concentrated it will be at certain parts of the face—forming high lights, and accentuating those parts, while the half-tones and shadows are held down to their proper weight. The larger the source of light the softer the effect, and the less we notice any one or more parts of the composition being of greater importance as compared to other parts.

Now we come to the operator who uses curtains or screens on his light, and I find by close observation that he differs but little from his brother who uses no curtains. In working his lightings he is governed by that most important of all considerations, the "direction" of his light, and after he has completed his lighting, and we examine it closely, we find that he has made but one difference, *viz.*, in the size of his light, he having curtailed it down until it is much smaller, but at the same time he has moved the subject farther to it, making, perhaps, a stronger or more bold effect, which is merely his own taste, judgment, preference, interpretation, or the requirements of the subject, call it what you may.

So we can arrive at but one conclusion, and that is, we must work the principle of the light and not for the method of obtaining it. 'Tis but folly for any one man to claim he has the "only way" of lighting the face." There is no such thing as "a way," but

"the thing" is to know the principle of it, and what matters "the way." It is just here so many of us have misunderstood our artist friends in their lectures at the conventions. They have undertaken to tell us the principles, and we cried out for "a way." The way must rest with each individual, and as soon as that individual has found the way he establishes his own individuality, and that individuality belongs to him and no other, but it must be founded upon the principles governing his work. What are the principles? That is too long a story. Perhaps at some future time I may try and tell of them as I understand them. But, as stated before, the "direction" of the light as it falls toward the subject is the first.—FELIX RAYMER, in "Wilson's Photographic Magazine."

New Apparatus, &c.

Raymer's Universal Lens Flange. Supplied by A. Raymer, 125, Eurlham Grove, London, E.

This flange or adapter forms a perfect connection between camera front and any one of a number of lenses, though they differ in diameter. It enables an operator to attach one lens in lieu of another with rapidity and security, avoiding the troublesome process of unscrewing the one and screwing on the second, or using the old and cumbersome mediation of extra lens boards. The system employed is an advance on those previously known, and may be briefly described as follows:—In a ring, having a rack cut on its circumference, a strong Iris diaphragm is enclosed. The size or diameter of the opening of the Iris is regulated by a pinion revolved in contact with a rack on the encompassing ring. So that the rear portion

of a lens tube (up to the shoulder) being introduced into the aperture of the Iris, the pinion is revolved and the strong leaves of the Iris firmly grip the lens tube. To make this grip doubly secure, a clamping arrangement is provided, which renders any relaxation of the hold on the lens an impossibility. The working portions of the mechanism are of suitable metal, but the external frame is of aluminium, so reducing the weight to a minimum. It is made in several sizes, the smallest taking lenses of 2 in. and less in diameter, and the largest will receive lenses of $4\frac{1}{2}$ in. and less diameter. We understand that Houghton, Limited, of High Holborn, and Messrs. Marion, of Soho Square, have taken up the agency for this piece of apparatus.

At the meeting of the Common Council last week the Southwark Borough Council applied for permission to remove the Obelisk in St. George's Circus in order that an ornamental clock tower presented to the borough might be erected in its place. This old landmark will be much missed by all South Londoners, and although the utilitarian aspect of the proposed substitute will have its advantages, the sentimental associations surrounding the Obelisk will be a strong factor in any opposition that may arise as to its removal.

Exhibitions.

R.P.S. HOUSE EXHIBITION.

THE exhibition of photographs by members of the affiliated societies selected from prints sent in to the 1904 competition was opened at the Royal Photographic Society's House, 66, Russell Square, on Tuesday, and, including as it does so representative and varied a collection of excellent examples of photography by some of the leading workers of the newer school, it ought to attract the attention it merits. By the newer school we do not mean the school of advanced, so-called art, photography, including largely the indefinite in aspect and motif, but rather the best class of "straight" photography as worked by the younger and virile exponents of camera craft, workers of whom we shall hear more anon. The exhibition consists of 52 photographs, carefully chosen from the great number originally submitted. These include fourteen landscapes, eleven portrait and figure studies, six architectural studies, seven seascapes, four natural history or flower studies, seven genre, and three street scenes. The varied character of the exhibits may well be judged from this analysis. The lack of frames, however, makes the show appear rather poor. We understand that the prints are to be suitably framed before being sent the round of the affiliated societies, and wonder why this could not have been done before they were shown at Russell Square. Curiously enough, the lack of frames did not appear to detract from the previous house exhibition, that of M. Demachys' gum prints, but rather to add to their effect. The explanation of this is probably because the whole of M. Demachys' prints were much of a size and very similar in tone and mounting. In the present instance they are of every variety of size, colour, mounting, and treatment, and, although admirably arranged on the walls, the tout ensemble is rather scrappy. Among so many good pictures—which include, we note, several that have been awarded the R.P.S. medal, although they do not score in this competition—it is somewhat difficult to pick out examples for special comment. The six photographs that were adjudged the best in the competition, and which were awarded the specially designed plaque, are: No. 47, "A Wind Sea," by F.J. Mortimer; No. 48, "In Arcady," E. T. Holding; No. 49, "The Foreman," T. Fitzgibbon Forde; No. 50, "At the Smithy," Edgar G. Lee; No. 51, "A Village Belle," Mrs. G. A. Barton; No. 52, "Evening," G. H. Capper.

To deal with these six first, "A Wind Sea" is probably as good a rendering of moving water as is likely to be secured by the camera, but for general forcefulness and abandon "In the Height of the Storm" (No. 46), by the same worker, is a better picture. "In Arcady" is a charming little half-length portrait of a small boy intently blowing a whistle pipe. The "action" and pose are excellent, the photography is exceptionally good, but the small boy is only blowing the pipe, he is not playing it. "The Foreman" is an admirable portrait study, full of vigour and character, but the lighting is rather one-sided, which makes the shadow side of the face rather heavy. "At the Smithy" is a fine rendering of sunlight. Two men and a horse at the smithy door, bathed in the light of the sinking sun. The more one gazes into this picture the more brilliant and real the sunlight appears. The shadows are full of detail and rich in colour, and the figures are well placed and posed. "A Village Belle" is in Mrs. Barton's well-known "large" style, which compels admiration. Mrs. Barton has mastered the secret of concentration of both light and subject, and the result has a certain breadth that is quite "painty" in effect. This picture, for simple, direct treatment, is as fine an example of portraiture as anything this clever worker has given us. "Evening" is rather a hackneyed subject extremely well done. The evening light shines through the drifting clouds of the darkening sky, and is reflected in the low-lying, marshy middle distance and glimmering river foreground. At first there appears to be a certain woolly, out-of-focus appearance about this picture that is somewhat displeasing at close range, but when viewed at a distance of a few feet the admirable lighting and delicate treatment remove this, and the picture stands as an admirable example of quiet landscape work. A review of the other pictures in the collection will be given next week.

ANDOVER.

THE fourth annual photographic exhibition held in connection with the Andover and District Horticultural Society was opened on

August 1. Probably the very worst time of the year was chosen getting together a provincial photographic exhibition—the time of when the majority of photographers are away on holidays, obtaining new pictures for the winter shows, and but little disposed to exhibit last season's work, and equally indisposed to exhibit their labours so early in the present season.

These facts, doubtless, will account for the rather small number of entries. The committee, however, has worked hard, and the efforts of Mr. W. I. Gradidge, the energetic Hon. Secretary, and willing co-workers ought to have a richer reward in the shape of a larger exhibition should they decide to hold another show in the season. The fact, too, that at present there is no photographic society at Andover may also have a little to do with the lack of pictorial support extended to the exhibition by local photographers.

The present collection of pictures mounted on screens in an arm of the main exhibition may, however, do something to foster the idea of forming a society in this neighbourhood. The judges, Messrs J. Mortimer and S. G. Kimber, made the following wards:—

Open classes.—A portrait or figure studies—Gold medal, "A Portrait," Miss Bessie Stanford. Silver medal, "A Veteran," J. Smith. Bronze medal, "The trivial round—the common task," Rev. E. G. Watts.

Class B.—Landscape and seascape—Silver medal, "Weeds and Rushes," A. MacDonald. Bronze medal, "Moreton Old Hall," W. Foxall. Certificate, "Morning Mist," A. Burley Moss.

Class C.—Architecture—Silver medal, "An Old Street, York," A. W. Wallburn. Bronze medal, "The Eastern Crypt, Winchester," W. A. Clark. Certificate, "Salisbury Cathedral, West Entrance," Rev. E. J. Watts.

Classes D, E, and F, open to amateurs only residing within a radius of twenty miles of Andover:—

Class D.—Landscape and seascape—First prize, "A Dairy Pasture," G. Vialls. Second, "Hoar Frost," Rev. E. G. Watts. Third, "Highland Loch," Miss M. Best.

Class E.—Architecture—First prize, "St. Pierre Church, Chichester," Rev. E. G. Watts. Second, "Pulpit, St. Lô Church, Normandy," Rev. E. G. Watts (debarred). Third, "A Fane in which I Pray."

Class F.—Figure studies, etc.—First prize, "Taking Soundings," Rev. E. G. Watts. Second, "Snowdrops," Rev. E. G. Watts (debarred). Third, "Group of Highland Cattle," Miss M. Best.

FORTHCOMING EXHIBITIONS.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.

September 16 to November 5.—Photographic Salon. Dudley Galleries, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Fortieth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-22.—Rotherham Photographic Society. Hon. sec., H. Hemmingway, Tooker Road, Rotherham.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 5, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. L. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

ember 2-8.—Southsea Photographic Society. Hon. Secretary, Lawton, 20, Clarence Square, Gosport.
 umber 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, 101st Street, New York.
 umber 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
 umber 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Per, Oakdene, Highfield, Southampton.
 umber 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.
 umber 14-23, 1905.—The Scottish National Salon. Hon. Secretary, A. Frame, 28, Bank Street, Hillhead, Glasgow.
 umber 20-21, 1905.—South Essex Camera Club. Hon. Secretary, Nichell, 180, Browning Road, Manor Park, E.
 umber 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.
 umber 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.
 umber 1905.—Northern Photographic Exhibition. Secretary, F. G. T. 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

ember 30.—"Photographic News." Quarterly Competition. Photographic News," 9, Cecil Court, Charing Cross Road, London.
 umber 1.—Thornton-Pickard. £100 cash prizes for pictures taken Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
 umber 10.—Luna paper. £240 cash prizes for prints on Luna paper. Luna Allegre and Co., 59a, New Oxford Street, London, W.C.
 umber 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.
 umber 31.—Coxin. 68 prizes for users of Coxin. Judging twelve prizes. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
 umber 1.—The "Graphic." £50 in cash prizes. Manager, Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.
 umber 31.—Barnet. Nineteen classes. Prizes valued at £500 lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.
 umber 15, 1905.—Ilford. £750 in prizes for negatives on Ilford paper. Ilford, Ltd., Ilford, E.

Commercial & Legal Intelligence

ROLITE, LTD., of 66, Berners Street, London, W., inform us they have taken over the Notkin Light and Power Co., of Edinburgh.

ICAL Business to be Relinquished.—Messrs. Eames and Comp., opticians and photographic dealers, announce their intention shortly relinquishing the business at 28, Rushey Green, Catford, the lease being for disposal.

RECEIVING order has been made in the case of Johnson Holmes, of 26, Clarendon Street, Wolverhampton. The debtor puts his gross liabilities at £1,372, of which £218 3s. 4d. is extended to rank as dividend for thirty-six unsecured creditors. One order is fully secured to the extent of £1,150. The assets he rates at £11 2s., leaving a deficiency of £207 1s. 4d. The causes of insolvency he attributes to "depreciation of property and bad management."

SUMMONS under the Pharmacy Act, Ireland, has been dismissed by the Collooney magistrates on the technical ground that the register of pharmaceutical chemists, chemists and druggists, etc., produced in court was not certified under the hand of the Registrar and countersigned by the president and two members of the Council. The defendant was an unregistered person, against whom it was found that he had kept open shop for the sale of poison. It is understood that a case for the High Court will be stated immediately.

RYEN COMPANY, LTD.—Registered July 22, by L. F. Hedger, of Camera House, 82-5, Fleet Street, E.C., with a capital of £1,000 in shares. Objects: To carry on the business of chemists, druggists,

opticians, manufacturers of and dealers in all kinds of salts, acids, alkalis, drugs, medicines, medicaments, herbs, pharmaceutical, chemical and surgical instruments and appliances, toilet requisites, photographic materials, scientific, surgical, and optical instruments, etc. No initial public issue. Registered without articles of association. Registered office, Byron House, 82-5, Fleet Street, E.C.

A GREAT Temptation.—At the Liscard Police-court on Monday last, before Messrs. H. Pooley and G. H. Peers, Mary Ann Curran (21) and Margaret Dunn (47), both Liverpool hawkers, were charged with stealing a package of photographic material, value 2s. the property of Mr. R. W. F. Robinson, chemist, Seacombe. It appeared that the parcel had been left by a messenger in the smoking saloon of the Wallasey ferry steamer "Lilly" on Saturday afternoon, instead of being handed to the stagemen for conveyance across the river. It was picked up by a little girl named Frances Ann Robinson, 38, Demesne Street, Seacombe, who intended to take it to the pay-gate at Seacombe Ferry. The two prisoners came up, however, and took it from her, telling her that they would give it to the man at the gate. They did not do so, and were afterwards arrested by Police-constable White, who found them tying up the parcel in Mersey Street, Seacombe. Mr. Pooley said it was a very improper thing on the part of the ferry authorities to allow parcels to be conveyed in such a loose manner, as it caused great temptation to unprincipled persons. Prisoners were each fined 5s., with the option of three days' imprisonment.

CAMERAS as Luggage.—His Honour Sir Horatio Lloyd has forwarded to the Registrar of the Holywell County Court his judgment in an action which he heard last week, in which Mr. Foster Smith, an assistant master at the Holywell County School, sued the L. and N.-W. Railway Company for £25 16s., damages for luggage lost in transit. The action raised an important point affecting amateur photographers and all who avail themselves of the "luggage-in-advance" arrangement. The plaintiff forwarded to Nelson a portmanteau containing, amongst other things, two cameras and other photographic apparatus of the value of £17. The portmanteau was not seen again. For the defendant company it was argued that they were not common carriers of cameras, and that an extra rate should have been paid. In giving judgment, his Honour pointed out that nothing was said on the consignment note signed by the plaintiff as to the exception of cameras. In these days it was by no means an unusual thing for passengers to carry such articles as cameras for their use and pleasure on the journey, and it seemed to him that the judgment of Chief Justice Cockburn in the case of *Macrow v. the Great Western Railway Company* would necessarily cover such an article as the one in question. His Honour therefore directed judgment to be entered for plaintiff for the amount claimed, with costs.

Patent News.

The following applications for patents were made between July 18 and July 23, 1904:—

Washing Apparatus.—No. 16,077. "An improved appliance for developing and washing photographic plates, films, and prints." Henry Woodhouse Fairbrother.

Films.—No. 16,177. "Improvements in photographic films." Austin Edwards.

Shutters.—No. 16,289. "Improvements in and relating to shutters for photographic lenses and other scientific instruments." Alexander Eugen Conrady and Frederick William Watson Baker.

Camera Carrier.—No. 16,322. "A new or improved camera carrier or support." Complete specification. Henry James Thomas.

SHORTLY before ten o'clock last Saturday evening a call was received at the Manchester Chief Fire Station, Jackson's Row, to an outbreak which had occurred in the premises occupied by a photographer at 15, Market Street. A detachment of the brigade was despatched, and after a few minutes' work succeeded in subduing the fire. Considerable damage, however, was caused to the property in the dark-room, but, fortunately, the adjoining portions of the premises were untouched. The cause of the outbreak is unknown.

News and Notes.

THE Weymouth Photographic Society's monthly outing took place on Wednesday last, when about twenty-eight members and friends availed themselves of a pleasant trip to Corfe Castle.

A PHOTOGRAPHIC society has been formed at Slough with Mr. E. Oetzmann as President and Mr. G. Young as Secretary. It will be known as the Slough Photographic Society, and will meet at the Leopold Institute.

THE Derby Convention Group of 1886.—We omitted, when reproducing this interesting photograph from the Convention Handbook a few weeks ago, to credit our old friend, Mr. Thomas A. Scotton, of Derby, with the production of the negative.

WATFORD Camera Club.—The second annual open exhibition of the Club will be held in the Corn Exchange on October 26, 27, and 28. Particulars may be obtained from the Secretary, Mr. H. G. Trayfoot, 3, The Parade, High Street, Watford. The final date for entries will be October 5.

No. 11 of the "Practical Photographer" Library Series has been sent us. This number deals with landscape photography. The pictorial work of Mr. Reginald Craigie comes in for review at the hands of the Editor, and many able articles are contributed by well-known writers.

AN Exhibition of Photographic Work is announced by the Kettering Church Institute to be held on October 18, 19, and 20. There are five open classes, and the awards are silver and bronze medals. Mr. W. R. Bland will be the judge, and Mr. E. Claypole, 112 Hawthorn Road, Kettering, is the Hon. Sec.

THE "Perfected" Enlargement Tables is the title of a price list of enlargements in Bromide, Platinotype, Carbon, etc., specially compiled for the professional worker by H. Holden, of 68, Oxford Terrace, Hyde Park, London, W. All who require enlargements made at a low figure should apply for a copy of this table.

MESSRS. SANDS, HUNTER, and Co., 20, Cranbourne Street, Leicester Square, London, W.C., have issued a new edition of their useful and popular second-hand list of photographic apparatus. This list should be secured by all photographers anxious to pick up cheap cameras, lenses, photo sundries, or other bargains. It will be sent post free for the asking.

MESSRS. SANDERS and CROWHURST, 71, Shaftesbury Avenue, London, W., have sent us their illustrated catalogue of photographic apparatus. It contains a very complete selection of everything needed for the ordinary photographer, as well as several excellent lines more particularly designed for the specialist. A postcard to the above address will bring a copy.

ENTRY forms for the Ilford and District Photographic Society's Exhibition are to hand. The exhibition will be held at the Reading Room, High Road, Ilford, on November 25 and 26, and one gold, two silver, and two bronze medals are offered in the open class. Messrs. J. T. Ashby and Furley Lewis are the judges. The prospectus can be obtained from the Exhibition Secretary, Mr. H. Cole, 160, Thorold Road, Ilford.

PICTURE post cards have taken a permanent place in our daily life, and infinite skill and ingenuity are concentrated on their production. No corner of the globe has escaped the man with the camera in his tireless search for views for postcards. Hartmann Post Cards, produced and sold by F. Hartmann, of 45 Farringdon Street, London, E.C., are excellent productions, and the latest publications from this firm show the wide field covered by the series.

THE South Essex Camera Club is holding its Third Annual Exhibition in the Town Hall, East Ham, on January 20 and 21, 1906. Silver and bronze medals are offered in the open classes, and special prizes in the members' classes. The judges will be Messrs. A. Horsley Hinton, H. Snowden Ward, and Rev. F. C. Lambert. All communications should be addressed to the Hon. Sec., T. Mitchell, 180, Browning Road, Manor Park, E.

WE have received an excellent little price list of Dr. Schleussner's plates and photographic goods. The book is admirably printed, sets forth clearly the merits of the plates, films, developers, manufactured by Dr. C. Schleussner at his dry plate factory Fort-on-Main. Messrs. Thos. Christy and Co., 4, Old Swan Upper Thames Street, London, E.C., are the sole agents for the United Kingdom. A copy of the list can be had on application.

THE Hon. Secretary of the London and Provincial Photographic Association is now preparing the programme of fixtures for the winter session, and will be glad to hear from members, interested members, or friends of members, who may have subjects of interest for discussion at the evening meetings, papers on photographic or lantern slides for display. The Hon. Secretary's name and address are Mr. R. J. Kindon, Burnside, Church Road, Shortlands, Kent.

A SENSITISING Bath for Carbon Tissue.—M. Vaucamps, writing the "Moniteur de la Photographie," gives the following as conferring a high degree of sensitiveness to carbon tissue:—Bichromate of potassium, 80 grams; hot distilled water, 1,000 c.c.; bicarbonate of soda, 2 grams; bromide of potassium, 1.5 grams. Mix in the order stated, taking care that the bichromate of potassium is completely dissolved before the other ingredients are added. Care must be taken not to use the solution until it is quite cold.

IN the "Journal" of the Royal Microscopical Society for July, Dr. A. E. Wright discusses the following four methods of measuring the magnification of a microscope and its elements:—(1) use of a focussing lens placed above the ocular for bringing the emergent rays to a focus in the plane of a suitable measuring scale; (2) separate measurements of the magnifying powers of objective and ocular; (3) measurements depending on Helmholtz's formula; and (4) measurements involving the production of a fiduciary phenomenon by means of a diffraction grating.

RECOGNITION of Camaraderie.—During the recent visit of the Queen and Queen of Great Britain to Ireland, and while on their way to Trappist Monastery on Mount Melleray, several amateur photographers were noticed taking snapshots at her Majesty, who, in spite of trying to foil them as some of lesser note are inclined to do, finally turned her camera on them. The daughter of the American President takes a different course. As guest of honour at a reception at the Women's building at the St. Louis Fair recently, it is reported that she noticed an amateur photographer aiming to take a snapshot at her, and on her complaint to the chief of the hostesses she had turned out of the grounds.—"American Amateur Photographer."

YARMOUTH in London.—Some idea of the excellent effort which the Corporation is making to induce more visitors to come to Yarmouth by appealing to the eye of the stranger, through the medium of pictures, is prominently placed in the Holiday Court at the Crystal Palace, where, gathered from a visit to the Town Hall, Yarmouth, where are on view for a few days a collection of fine photographs executed on a large scale. There are nineteen in all, finely framed, and embrace all the features that have made Yarmouth so popular. They are the work of Mr. Yallop, of Regent Road, Yarmouth, and are hung on either side of an artistic panel, on which the opportunity is taken to offer a few recommendations in Yarmouth's favour.

MODERN Stage Effects.—Herr Eugen von Jemmendy, the manager of the Opera House in Buda-Pesth, is about to introduce a series of scenic innovations in Wagner's Nibelungen, which will greatly add to the realism of the performances. According to the correspondent of the "Standard," Herr von Jemmendy has invented a process whereby the movement of the Rhine waves in the Rheingarden is exactly reproduced. For the "Walkürenritt" the artist has taken instantaneous photographs of eight female circus riders dressed in Valkyrie costumes, and rode in front of a backdrop of a boarding six hundred yards in length. These are to be cinematographically thrown on the stage. The effect produced is the riders bursting out of the clouds and riding in the air. The Morgana scene in the last act of the Queen of Sheba has also been made very realistic by the aid of the cinematograph, a circus of riding the horses, camels, elephants, and Arabs, seen in the distance as a caravan crossing the desert.

THE death of Mr. F. Goodall, R.A., last week leaves a blank in the rapidly thinning ranks of the old school of workers, that newer elements to academic honours do not quite seem to fill in the public eye. It is unnecessary to speak of his pictures and their characteristics, since every visitor to the Academy at any time during the past twenty years remembers them well—works showing much trained ability, but no kind of inspiration. Mr. Goodall, however, did not confine himself to Egyptian scenes. He had always shown a readiness to turn his hand to a variety of subjects, and, just as he had changed from British rustic pictures to the Nile and the Pyramids, so he passed from those to Biblical scenes and to English landscape.

THIS year's meeting of the British Association for the Advancement of Science, to be held at Cambridge from August 17 to 24, promises to be one of exceptional interest. Copies of the programme of proceedings are now ready, and may be obtained on application to the local secretaries at Cambridge. Mr. Balfour will deliver the inaugural address in the Corn Exchange, at 8.30 p.m., on Wednesday, the 17th. The University town is a peculiarly appropriate place of assembly at a time when molecular and mathematical physics hold so prominent a place in the field of science, especially in connection with the theories of electricity and radio-activity, in the elucidation of which Cambridge professors have done some of the finest work.

THE thirteenth annual session of the National Union of the Photographic Societies of France, the twelfth session of the International Union of Photography, and the congress of the Lorraine Society of Photography took place this year at Nancy from July 18 to 25. The delegates—a hundred strong—were received at the Hôtel de Ville by Beauchet, Mayor of the town; M. Janssen, director and founder of the Mont Blanc Observatory; M. Pector, Secretary of the Photographic Union; and M. Bucquet, President of the Photo Club de Paris. The excursionists visited the principal industrial establishments of Nancy, and a grand soirée was held in their honour. Various excursions, including visits to Toul, St. Nicholas, the Vosges, and Rembouurg, filled the week's programme.

GLoucestershire Photographic Society.—A field day in conjunction with the Gloucester and Stroud Photographic Societies was held on Thursday, July 28, to Gloucester, Deerhurst, and Tewkesbury. The party embarked on the s.s. Berkeley Castle and steamed up the river. The first stopping-place was Deerhurst. This interesting ancient church and Saxon chapel was visited and a number of plates exposed. The party then returned to the boat and proceeded to the Lower Lode Hotel, where lunch was served, after which the ferry was crossed, and a short walk brought the party to Tewkesbury, where the Abbey, old houses, etc., received careful attention from the cameras. Over two hundred plates were exposed, and great credit is due to the Gloucester Society for the excellent arrangements made.

MINIATURE PAINTING.—The news that the Princess of Wales has been ordered to a young lady miniaturist to paint a portrait of the Prince George reminds one how popular this form of portraiture is becoming. Already the other four children of the Prince of Wales have had their miniatures painted—the King having them specially done to present to the Prince and Princess upon their return from their Colonial tour. A departure from the same idea are the miniature panel portraits, done in pencil, the heads alone being coloured, the drawing of the figure being left in pencil, making a charming effect. Miniatures are being used now for fitting into the links of watches. Carved ivory portraits also claim the attention of Society beauties who have grown tired of artistic photography and life-size portraits.

STREET STUDIES.—Amateurs living in great cities often bemoan their lot in having nothing to photograph as compared with those who are the possessor of the camera who live amid rural surroundings. As a matter of fact, says the "Weekly Budget," the dweller in big cities has around a plethora of material from which to build up some of the most striking photographic pictures. It is hidden from his eyes because it is so often seen; the common soon becomes the commonplace. But, given an artistic eye, there is no street in a great city which does not teem with pictorial subjects. For example, it has been shown of late what a wealth of unique pictorial material the busy eye can observe in the doings of the men who tar our roads or

asphalt our pavements. By waiting near the copper in which their evil-smelling decoction is boiled it will often happen that the ascending smoke will provide a most artistic effect.

ART as a National Asset.—The "Burlington Magazine" for August urges the necessity of better artistic training from a commercial point of view. It says:—"Have we all realised, for instance, how much France and Italy have profited in hard cash by the taste, consistency, and liberality of their patronage of art, compared with a country like the United States, where not one man in a thousand takes even a superficial interest in it? Their cities are visited by hosts of travellers and students from all parts of the world, whose board, lodgings, and railway fares alone would amount to an enormous sum annually. To this must be added the huge sales of works of art which their national reputation enables them to effect." But it is not enough, we are told, to train artists and designers. The public also must be educated to appreciate good art and to dislike bad art; and that may be done, the "Burlington" thinks, by a thorough reorganisation of our picture galleries and art museums, where good and bad work is now too often indiscriminately mingled.

BOTH at home and abroad, but more especially in their travels in foreign lands, amateurs are often anxious to secure a photograph of memorial stones let into the floors of churches or of floors themselves which are remarkable for the beauty of their mosaic work. There are right and wrong ways of taking such photographs, says a writer in the "Westminster Gazette," and perhaps a hint as to the right way will save some of my readers the disappointment of useless negatives. He says: The hint was given me by a verger of Winchester Cathedral, who was watching my efforts to take a photograph of the slab of dark stone which marks the resting-place of Jane Austen. The task seemed nearly impossible of execution, inasmuch as the surface of the stone caught the light in such a way as to make the inscription almost invisible. But the verger soon overcame the difficulty by directing me to a corner of the cathedral where stood a bucket of water and an old cloth, and instructing me to wipe the stone over with water. In a moment the inscription stood out with startling clearness, and the negative was wholly satisfactory.

MODERN Artists out of Fashion.—The gates of Burlington House closed on Monday night on this year's Royal Academy exhibition of paintings. For most of the artists, so far as the sale of their exhibited works is concerned, the results are described as "wretched," only 130 pictures among some 1,200 having found purchasers. The depression is not confined to the Royal Academy; other picture galleries tell even a worse story. A well-known Academician was questioned on the subject by an "Express" representative. "I believe," he said, "that wealthy people are limiting their picture buying to old masters. They will not look at modern pictures, simply because modern pictures are not the fashion. I often wonder how many artists can be now making the smallest kind of living. They are all driven to painting portraits, and the result is a very distressing competition, in which the weak go to the wall—and the strong go to the 'line.'" Mr. H. Riviere, the rising young portrait painter, who was also seen by an "Express" representative, threw further light on the question. "Many people buy pictures as an investment," he said, "and with the example of recent sales of modern pictures at Christie's and elsewhere before them, they are afraid of investing in modern works. Many modern pictures bought at £1,000 have changed hands recently for £50. I attribute the undoubted rage for old masters to-day to be a mere whim of fashion. Fashions come in cycles, and I have no doubt it will be the turn of modern pictures again before very long."

SOME More Over-the-Counter Stories.—Several of our customers have been good enough to send us accounts of peculiar inquiries that they had, and we are retailing them for the benefit of our readers. Says "Houghton's Monthly," One dealer tells of a customer who had always been in the habit of using matt surface gaslight paper, and had never used anything else, until one day he decided to try and make a few prints on ordinary P.O.P. Having purchased a packet, he went home to make his first experiments with a daylight printing paper. The next day he went into the dealers for some more gaslight paper, and incidentally remarked that he was going to give up P.O.P. work, as it was too slow, to say nothing of the poor weak image that resulted from a whole day's printing. The dealer thought

something must be wrong, and asked to see the prints. Then the mystery was explained; the paper had been put in back to front, the customer explaining with an air of resignation that he thought that the "glossy stuff on the back was some new sort of adhesive coating to fix the prints on the mounts." Even P.O.P. printing is a sealed book to some people. The story of the lady who expected to get a visible image when she printed gaslight paper is evidently a more common experience. For instance, we are told of one who complained that there must be something wrong, because she had exposed the paper for as many seconds as instructions stated, and then looked at it, and finding no image she tried it with a ten-minute exposure, only to get the same result. Finally, in desperation, the frame was left up close to the gas for over two hours, and, as no image appeared after all that time, the poor dealer was applied to, and asked to change the paper for a more reliable variety.

POTATOES AND PHOTOGRAPHY.—A Chinese vegetable dealer in Sydney is displaying a taste for photography. His name is Ah Sin, and one of the leading photographic dealers in the city has explained how the bland-featured Celestial came one day into his shop and invested in a hand camera, with all the other requisites necessary for picture-making. How he came to be fired with a desire to go in for photography could not be ascertained. This much, however, was certain—that although only a vegetable hawker he got to know as much about cameras as cabbages; and, mastering the chemical manipulation involved in the business, eventually became remarkably proficient in the art. Asked one day who had shown him how to take photographs, he smiled expansively, and simply said, "Oh, a fliend." Whoever the "fliend" was he certainly must have found Ah Sin a very apt pupil. On his morning rounds now, we are told, John is never without his camera. There, on top of the pumpkins and cabbages and potatoes lies the little kodak, fully loaded, and ready for the first thing that comes along in the picture-making line. But there is a purpose in John's photography, for while he takes his customers' photos he takes their money too. Potatoes and photography! A queer combination, truly, but Ah Sin troubles little about the incongruity of the thing so long as he continues to make nearly as much—as he does—out of one as the other. None of Ah Sin's fellow-countrymen, however, have yet shown any signs of becoming afflicted with the camera craze, and if cabinet-making and the grocery and greengrocery business are avenues of industry in which the Celestial is successfully competing with his European brethren in Sydney, the photographic profession need not have any fear of a Chinese invasion.

PHOTOGRAPHIC CLASSES.—The Acton and Chiswick Polytechnic, Bath Road, Bedford Park, London (Turnham Green Station), will shortly again conduct an interesting series of evening lectures and practical classes in photographic subjects. The session commences on September 26, but application must be made for entry forms at once. The instruction is in three divisions. On Monday, September 26, and subsequent Mondays until April, a course of lectures (with demonstrations and practice) will be given in pure photography, including portraiture. On Tuesday, September 27, and subsequent Tuesdays, a practical course on retouching, accompanied by illustrated lectures. On Thursday, September 29, and subsequent Thursdays, the process work will be continued, and photo engraving (the production of blocks in line and in tone) will be demonstrated in practice, but this session will be accompanied by illustrated lectures or short chats on the theory of the production of the correct line and dot; negative making by wet and dry collodion and with gelatine emulsion; various methods of etching, and an outline in the practice in making and finishing the block and proving. The classes, especially the retouching and photo-engraving classes, are limited by the space at their disposal (a tender consideration for the students, which we recommend to other Polytechnics), and immediate application should be made to the Secretary for entry forms. The first class nights named above will be free to all intending students. The classes will be open to students from any part of the county of Middlesex. This Polytechnic is governed by a Committee, which is directly responsible to the Middlesex County Council. Examinations in connection with the City and Guilds of London Institute will be held in May in the subjects of pure photography and process, and any students who desire it will be prepared for the same.

PHOTOGRAPHY OF METEORS.—Perhaps at the present time, when we are approaching, under very favourable conditions, the annual play of Perseids, which lends itself to amateur observation to great advantage than any other shower, a few hints may be acceptable to those who have had no previous experience of this class of photography. The following suggestions by T. H. Astbury in the number of the "English Mechanic" are likely to be helpful:—The darkness sets in it would be well to arrange a table or other support for the camera, which should be directed to the sky at an elevation of 50 deg. or 60 deg., and preferably towards central land. To assist identification it would be well to expose upon a constellation including some fairly bright stars. The camera should be focussed in daylight upon the most distant object available, clamped just *within* that focus. The sun would serve, but it is recommended to those who value their eyesight for telescopic work. Rapid plates should be used, and the greater the aperture the better. At about ten o'clock the plate should be exposed, and the time noted to the nearest minute. *Constant* watch must be kept upon the region selected, and, if a brighter meteor is seen cross that portion of the sky, the observer should note, as exact as possible, the points among the stars where the meteor flight appears to begin and to end, and the time of apparition. The camera should be closed after about thirty or forty minutes' exposure and the closure noted. Another plate may then be exposed, bearing in mind the absolute necessity of a *constant* watch and of exact notes. Development should be slow, and prolonged until the plate begins to darken over. Success will be indicated by a *straight* black line indicating the meteor trail, while the stars will be represented by lines more or less curved. Though the chances of success are greater on August 10 or thereabout, observations secured on the evenings of the week preceding and following would be of still greater value.

Mr. E. LANDOR, one of the cleverest animal photographers, recently disclosed the secret of his successful cat studies to the readers of "Cassell's Penny Magazine." After dispelling all the notions that the taxidermist and hypnotist are responsible for some of the poses, he proceeds to show that as much depends upon the temperament of the cat as on the fitness of the operator and his apparatus. The cat's nature, whims, and fancies must be studied and patience, and persuasion, not force, will do the rest. The selection of the cat is a most important matter, the nocturnal serenader posing few qualities that make him suitable for a study. Kitten is the best sitters, but they also require patience. Mr. Landor says that owing to their restlessness there is nothing to do but to wait, in fact, until the table on which they are placed is the only unexplored place in the room. Of course, that is to be examined, but by this time there is a dawning hope that something may be done. Here comes in the use of a confederate. It would be utterly impossible for one person to attend to both kitten and camera. If the former were open to reason, and could be persuaded to understand what was required of them, things would go smoothly, but they are such flighty morsels. Just as their attention appears to be fixed on the object before them, a sudden thought strikes them that a particular spot in the room has been overlooked, a bolt is made for it. Then comes a regular stampede, and the confederate has hard work to prevent a total evacuation of the table, and all the process of arrangement has to begin again. Patience, therefore, is not only a virtue, but a necessity. A means for holding the kittens' attention must be found, and to this end an assortment of objects is necessary, for what will attract one may not appeal to the other. They must be led to believe that the photographer is their best friend and not an evil-disposed person. The background must be of a general character, in order that it may with any slight alteration in the pose of the subject allow of similar alteration in the title of the study. The shutter must at all times be within reach of the operator, as a single second may make all the difference between success and failure. Among the most attractive objects Mr. Landor suggests a bunch of Pampas grass. If such articles as a metronome or a pendulum are used to attract attention, the vibration must be comparatively slow as the kittens are bound to nod their heads and eyes in following the object backwards and forwards. It is needless to say that stereotyped instructions can never be carried out to the letter, and that much of the success in this fascinating branch will depend upon the operator's skill and resources.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Society.	Name of Society.	Subject.
Bowes Pk. and District Ph. Soc.	Outing.	Potters Bar, Mimms, and Shenley.
Southampton Camera Club	Print Competition.	
Nelson Photographic Society	Time Development.	Mr. Woods.
North Middlesex Photo. Soc.	Informal Meeting.	"Portraiture" and
Watford Camera Club	Competition — "Figure Studies."	

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held July 28. Mr. P. R. Salmon (Author of a Photographic Trip to Greece and the Holy Land) in the chair.—Mr. Teape exhibited three plates exposed under Chapman Jones Plate Tester, No. 1 Westendorp backed, No. 2 Seed Ortho, No. 3 Imperial. No. 1 showed considerable halation, showing that the burnt sienna backing is not efficient, the sensitiveness to red and yellow is very great. No. 2 showed sensitiveness to green and yellow, but not much to red. The curious part is that the colour sensitised plates have exactly the same sensitiveness to blue that the ordinary plate No. 3 has. Mr. A. Bedding had also found that blue sensitiveness was the same for ordinary and colour sensitive plates. Mr. A. L. Henderson gave an interesting exhibition of slides illustrating Athens, its monuments and ruins. The Chairman said that the slides shown were probably the best shown in that room, an opinion that Mr. Freshwater shared. The Hon. Secretary announced that the winter programme was in course of compilation, and suggested that members undertake to open discussions instead of reading papers, and hoped that intending speakers would send in their applications at once.

The Paris Academy of Science has awarded the Lecomte prize of 10,000 francs for the most interesting work in physical science. Professor Blondlot for his researches on the N-rays.

Alcohol for Industrial Purposes.—The Chancellor of the Exchequer has been asked by Colonel Denny whether any facilities are given for the manufacture of alcohol for industrial purposes under special regulations, so as to make the duty as small as possible. He has also been asked by the same hon. member what is the minimum duty charged upon alcohol after denaturation, and how this duty compares with that exacted in Germany, France, Belgium, Holland, and Italy upon spirit used for industrial purposes, including alcohol for the manufacture of dynamite. From the lengthy reply made by Mr. A. Chamberlain it appears that there are no special facilities given for the manufacture of alcohol used for industrial purposes. There is no duty charged upon spirit of British manufacture used for methylation, or for purposes sanctioned under Section 8 of the Finance Act, 1902, but upon foreign spirits so used a differential duty of 5d. per proof gallon is charged. About three years ago the Board of Inland Revenue obtained through the Foreign Office information as regards the terms on which alcohol may be used for industrial purposes in the principal countries of the Continent and in the United States of America; and, so far as they can judge from the returns then made, duty is charged upon alcohol so used in any of the countries named. However, says Mr. Chamberlain, difficult to say whether this would be true in all cases, as in some countries the tax on alcohol is a single tax, but a combination of several duties chargeable at different stages of manufacture or of sale, and it is not certain that any of these are remitted in all cases of use of alcohol for industrial purposes. The Chancellor of the Exchequer, in the course of his speech in a lengthy debate in the House of Commons on Monday last, said the fairest and wisest course would be to appoint a committee to go into the whole question of duty-free alcohol. This matter will be watched with considerable attention by the photographic fraternity, alcohol being of such considerable use and importance in various photographic manufactures and manipulations.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by our correspondents.

ORTHO PLATES.

To the Editors.

Gentlemen,—Your article in "Ex Cathedra" last week re "Ortho Plates" recalls the fact that many years ago, when I was first in the throes of emulsion experimenting, I was the means of introducing in the market a perfect form of separator made in this country. On referring to my notes I find the following formula (it may interest experimenters) given to the members of the L.P.P.A. in 1887.

"Isochromatic plates:—To each ounce of finished emulsion, add 31 of ammon carb. solution (5 grains to the oz., which is saturated with washed carb. of silver, and 30 minims of ethrosenes, 31 to oz. This may be made in gelatine, and the supernatant liquid, etc., removed by the separator. This gives good results without a screen."

—Yours truly,

A. L. HENDERSON;

Brighton, August 2, 1904.

DEVELOPERS WITH ACETONE.

To the Editors.

Gentlemen,—With reference to the article on page 668 of your last issue under the above title, allow me to point out that Mr. T. Thorne Baker, F.C.S., is quite wrong in stating: "According to Eders-Jahrbuch for 1903, C. W. Czapke experimented previously to Lumière with acetone"; what is said is, "C. W. Czapke versuchte das vor längerer Zeit von Lumière und Seyewetz empfohlene acetone, etc." which is more correctly translated by, "C. W. Czapke tried acetone, recommended a long time ago by Lumière and Seyewetz," which puts a totally different complexion on the affair.

I should also like to state that I fail to see how the diagram reproduced on p. 669 illustrates "the difference between the character of gradation obtained with two H. and D. strips," considering that one was developed for eight minutes and the other for only three; surely, to have true comparison, the times of development should be the same. As the diagram now appears, A strip had only an exposure of six, while B had 32. If this was so, then the conditions of experiment were not fair; if the exposures were the same, then the times of development should have been the same, otherwise the conditions are not fair, and the result tells us nothing.—Yours faithfully,

LEONARD SMITH, F.C.S.

Norwood Junction.

TRADE LISTS WANTED.

To the Editors.

Gentlemen,—I venture to ask if you will favour this Society to the extent of mentioning in your journal that we are desirous of bringing our register of price lists, circulars, and booklets from firms in the United Kingdom who manufacture and supply photographic material, lens, outfits, etc., thoroughly up to date, and that we shall be glad to receive new issues of lists from time to time. All such will form part of our reference library.

Thanking you in anticipation,—I am, dear sirs, yours faithfully,

T. R. PRATT, Hon. Secretary.

Photographic Society of India,
40, Chowringhee, Calcutta,
July 12, 1904.

A CHILD'S Freak.—On Saturday evening the two-year-old daughter of Mr. Howells, photographer, of Windsor Road, Neath, in her childish ignorance, swallowed the contents of a bottle containing corrosive sublimate. Happily the act was observed, and a cyclist messenger was despatched for Dr. Lewis, who jumped on his own cycle, and within a few moments was administering an antidote. The child is likely to recover.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- F. Higdon, 129, High Street, Street, Somerset. *Photograph of Lightning.*
- G. W. Morgan, Cairnquhuen, Aberdeen. *Photograph (Combination) Containing Officials and Stationmasters of the G.N. of Scotland Ry.*
- J. W. Garratt, 9, Station Road, Ashley Down, Bristol. *Photograph (Combination) containing Muller's Orphanages, and Two Groups of Children and Attendants, Ashley Down, Bristol.*
- T. Wallace, Eskbank Road, Dalkeith. *Photograph of Exterior of Newbattle Church, Midlothian. Photograph of Interior with Communion Plate.*

A. SOPER.—MESSRS. Kelly, Holborn, London, publish such a list.

ADDRESS WANTED.—CHESHIRE asks: "Will you kindly give address of Mr. A. Pumphery, photographic publisher, late of Stanhope Street, Birmingham, to which address we wrote a week ago, but had letter returned, marked 'Gone.'" In reply: The above is the only address we know.

ADDRESS WANTED.—Can you tell me the address of Mr. H. P. Robinson, and of the publishers of his book, 'The Studio and what to do in it'?" In reply: Mr. Robinson has been dead some few years. His books may be had through any bookseller, or through any of the photographic dealers.

INDIAN JOURNAL.—SENIOR AND Co. ask: "Will you kindly give us the name and address of the 'Indian Photographic Journal'?" In reply: There are two Indian Photographic Journals. They are, "The Journal of the Photographic Society of India," 40, Chowringhee, Calcutta, and "St. Veronica," 2, Marquis Street, Calcutta.

COPYRIGHT QUERY.—HOLDER OF COPYRIGHT asks: "Will you please answer me the following question, viz., That a photographer having issued a series of picture post-cards of which he holds the copyrights, can another person take the same views and also issue post-cards and sell in opposition provided the second person takes the negatives himself and reproduces from his own work?" In reply: Yes, certainly he can. There is no copyright in the scenes.

DEALERS' TERMS.—CAMERA asks: "Will you kindly inform me how to procure dealers' terms, as I wish to open a shop to supply photographic materials?" In reply: We advise you to write to one of the large wholesale houses, such as Houghton's, Marion's, Fallowfield's, or Butcher's, whose addresses will be found in our advertising pages, stating your intentions and requirements. They will be pleased to open an account with you and send you trade terms on receipt of satisfactory references.

LENS QUERY.—E. NEGUS says: "I have a half-plate stand camera, which is a very good one, and when photographing a big group I fail to get them all in focus. When I've got the front sitters in focus the back ones are out of focus. Would you be good enough to state the reason? The lens I use is marked 'F.6 Focus 7-25 in.' Would you kindly tell me when taking a snap-shot of a procession with same camera how I am to focus to get it all clear?" In reply: The only way by which you can get objects situated in different planes in focus on the plate is by stopping the lens down. The one you are using

is short in focus for the half-plate size and will require a stop to get all parts sharp.

COLLOTYPE.—G. M. AMBROSE says: "I have been trying to work ColloTYPE process for post-cards, as per instructions given in 'B.J.' a few weeks ago. I have carried them out to needle's point. The results are all alike (mottled). I say what you think is the cause and how to remedy. I used six different plates of all the enclosed cards; they are all mottled. I have used glass of all grades and the results are all alike." In reply: Unless we saw you working we could say where you have gone wrong. You must bear in mind that the ColloTYPE process is not one to be learnt by a brief article and experimenting with half-a-dozen or so, though it is a simple process when once learnt. We should advise you to get a work devoted to the subject such as "Practical ColloTYPE," by A. W. Fithian.

COLOR PHOTOGRAPHY.—ELERHAS writes: "Reference page 'B.J.' of January 1, 1904, article by Mr. J. Rheinboldt 'Photography in Colours,' would you kindly inform me Where can such a screen of 300 lines to the inch with 0.001 inch interspaces be obtained? (2) What would be the price for a screen, say, 2½ inches square? (3) Would a Thorp Cell Diffraction Grating be suitable, or must the screen be made of glass? (4) What is meant by a 'decentred lens'?" (5) Would be the total length of apparatus if A had a focal length of 5 inches and B of 6 inches?" In reply (1 and 2) Messrs. Peacock and Co., Farringdon Road, would probably supply such a screen and quote you price. (3) We should think it would be better to use a screen of glass. (4) We should suggest that you employ the lens and prism as the writer seems to give that system the preference. (5) This will depend upon the size the picture is made, whether enlarged or reduced.

COPYRIGHT QUERY.—J. T. B. writes: "I should be obliged if you can advise me on the following. Two months ago I registered four photographs, which were views of this town. Since then these photos have been copied and reproduced as collotype views, without my consent, by a stationer in the town. I told him I should take proceedings against him for stealing them, but he told me I could not prevent him, and he would continue to sell them. I consulted a local solicitor, who informed me that I could not get an injunction to prevent the stationer from selling them for less than about £60. I would like you to inform me if that is so? For I am loth to believe that after seeking the protection of the Copyright Act, I should be compelled to pay such a sum of money to defend myself from such piracy." In reply: If you hold a legal copyright in the pictures you can certainly prevent the sale of the pictures, also recover penalties, damages, etc. We should advise you to consult a solicitor who is well up in the law of copyright. You should bear in mind that it is the loss of the suit who has to pay the costs.

With this number of the JOURNAL is presented a key list of group of members of the Nineteenth Annual Photographic Convention of the United Kingdom assembled at Derby the week July 11th to 16th.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854.

PUBLISHED EVERY FRIDAY.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued a two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose continuing the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

*** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that this year's entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1 next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA.

The British Association Meeting at Cambridge.

Of late years the papers read at these meetings have not contained much to interest the photographer; but at this forthcoming meeting there is quite a plethora of subjects allied to photography or interesting to photographers. Thus there will be a discussion on "The Radio-Activity of Ordinary Matter," one on "Standard Wave-Lengths of Light"; one on the "Units of Meteorological Measurements," in view of recent promised developments in this direction, will not be without interest. Professor Larmor is to make a communication on the laws of radiation in the solar system, and Professor Rubens on the optical qualities of metals. Professor Wood is to contribute papers on anomalous dispersion and colour photography. A popular afternoon address on radiation in the solar system is promised from Professor Poynting.

Discovery of an Alleged Old Master.

Pictures by the Old Masters are from time to time being found in most unexpected places. But it does not always turn out that all that are alleged to be by them are genuine. The latest discovery, according to a paragraph that has been going the round, is that an oil painting of "Christ Appearing to Mary after the Resurrection," believed to be the work of Vandyck, has been discovered at Grimsby. Upon the canvas the signature, "Vandyck, 1617," was found painted, in Old English characters, on the fabric beneath the corner of the wooden stretcher. This, of course, may be a genuine Vandyck, and if so we congratulate its owner. There is no question that there are many old and very valuable pictures in existence, often in humble dwellings, upon which their owners set no value, simply because they are unaware of it. For example, one may have been handed down from generation to generation, and simply looked upon as something to fill wall space. Then, perhaps, some one comes along, sees it, and purchases it "for a song," and afterwards sells it for a very substantial sum. But such cases are rare nowadays; still, they occasionally occur.

* * *

The Camera in the Auction Room.

"The worth of anything is just as much as it will bring," wrote Butler some hundreds of years ago, inspired by the muse of Ludlow Castle, well remembered by the Shrewsbury Conventioners, and if we are to apply the proposition to a recent incident it would show a marvellous depreciation in the photographer's stock-in-trade. It is not generally known that the railway companies hold periodical sales of the various articles left in their carriages by careless owners, and remaining unclaimed for twelve months; and

it is astonishing what bargains are occasionally to be picked up, if a bargain-hunter cares to wait till something "turns up" that meets his fancy. There has recently been held one of these auctions, one particular lot in which recalled to our mind the couplet from *Hudibras* just quoted. After a number of "lots" had fallen to the hammer, from a sackful of odd gloves to a brace of umbrellas, there was one of mixed character, the descriptive list of which included a number of useful articles of everyday life, and ended with a "valuable photographic camera." The whole lot changed hands for 23s.1 However, perhaps the "valuable" was merely the auctioneer's playful mode of describing the instrument.

Photographers A natural sequence of ideas leads the mind from the question of depreciation and Income Tax.

to thoughts of the man whom few care to see—the income-tax collector, though as regards this we may say we once knew a gentleman who said he enjoyed paying income-tax! There have been exhibitions at the Aquarium—now shorn of all its ancient glories—who, amongst other feats, appeared to enjoy a meal of broken bottles and window panes. *Chacun à son gout*, and the taste of few of our readers, we opine, will lie either in welcoming the income-tax man or ingesting spoonfuls of glass. The thought that the course of our remarks suggested to us was that, however much a photographer's stock-in-trade became depreciated—those who deal in photographic materials know the extent of this—he could make no claim for reduction of his tax in consequence, that being a question of capital, not of income, and, similarly, in the highly improbable event of the said stock increasing in value, his assessment could not be increased therefor. But this particular aspect of the subject is the least important of those presented to the professional photographer, especially in times such as those we are passing through. There has undoubtedly, to use the commercial jargon of the day, been a slump in photography for some time past, and one which at present does not seem likely to end. Many businesses which, to our knowledge, have for some time been carried on very profitably, showed in last year's balance-sheet an actual loss instead of the accustomed credit balance. Yet the unfortunate photographer has had to pay, for, as ought to be generally known (but which is not), the assessment for income-tax is founded on the average of the preceding three years' profit. Hence, though a man may find when he makes his accounts up that he has worked at a loss, his tax still is called for, and has to be paid, unless, indeed, he is so forward with his bookkeeping as to discover this in time to present his case to the surveyor before the tax is paid. But, even though the loss might not be great enough to cause the three years' average to bring him within a claim for entire exemption, or even partial exemption, the law has provided an important relief. Anyone suffering such loss in the working of his business for the last year may throw over the principle of average and elect to present the accounts of the year of loss only; then if he can prove to the Commissioner's satisfaction that this loss did occur, he is entitled, upon claiming return in due form, to have the whole of his tax returned. We have been reminded of this by a professional man with whom we have been recently associated. His profession is a most novel one, and there are very few who have taken it up—it is that of an "Income Tax expert," his business being to aid people in obtaining a return of tax paid, but for which they are not really liable, and we have been surprised by his account of the many ways in which his services have been required, and of the difficulties placed by the officials in the way of applicants for such return. *Verbum sap.*

Mirage; or Fata Morgana.

The "Standard's" Berlin correspondent telegraphing one day last week, says several cases of mirage, or fata morgana, have been seen in different parts of Germany. He states that at Friedrichstadt the inhabitants were astonished to see, during evening a day or two before, the reflection of a sea, studded with numerous islands, in the sky, and that the spect was very vivid, and lasted for twenty minutes. Also in Warnemünde, shortly after sunset, a whole town, with houses, towers, etc., was observed just above the horizon. The outlines of the different buildings were very sharply defined for about an hour, when the vision gradually disappeared. Since then, letters from correspondents have appeared in the same paper, saying that similar phenomena have appeared at different times here, at Hastings, Guernsey, for example. Now mirages are by no means uncommon in the Alpine districts and other places, it seems a pity that, as a mirage when it appears lasts for a considerable time, it has never been photographed; there should be no difficulty in the matter. Yet we have never seen a photograph of the fata morgana. It would, of course, be very easy to produce a "fake" photograph of a mirage by printing in from a second negative an image on the sky of a print from the first. Indeed, very fair imitations of mirages are sometimes accidentally obtained when two exposures are made on the same plate. However, it would be exceedingly interesting to see a genuine photograph of a mirage, and it should be easily obtained when one is seen, for it usually lasts long enough for an apparatus to be procured, if one does not happen to be on hand just at the moment.

National Art Competition.

There is no question that art and art teaching are spreading in the United Kingdom thanks in great measure to the Board of Education. This is now on exhibition at the Victoria and Albert Hall prize-winning works sent up by schools of art and classes all over the Kingdom. The gallery, it may be mentioned, in which they are shown is an upstairs room of the Indian Section in the Imperial Institute Road. The works sent in for competition this year were about a third less than last year; but, notwithstanding that betwixt forty and forty-one thousand had to be weeded out, and it was found that a larger number were found worthy to compete than was the case last year. It is noteworthy that this year there were nine works that were up to the medal standard, whereas only four reached that standard last summer, and five in the previous competition. In this year's competition modelling from the antique and from Nature met with much approval on the whole, two medals were awarded to modelling of design. It is a little strange to see from the report of the judges that for eleven years no drawing of a full-length figure has come up to gold medal standard. Mere studies surpass even last year's good show, but not even silver medal has been arrived at in paintings of heads from life, and a few of the flower and still-life paintings were found worthy of prizes. It may as well be mentioned that the chief purposes of the schools of this competition is to further the study of crafts, and, naturally, attention is directed to the design of designs for textiles and the like, and in some direct there were marked improvements—in others not. Students at the Royal College of Art ceased to enter national competitions, there has been no means of judging their attainments. These, however, are found, now their work is collected in the iron buildings behind the Natural History Museum, to be of a high order, embracing almost every kind of design, from large mural lunette to the daintiest laces. As might well be expected, there is a more general feeling of certainty and more maturity

work of the students of the college than in those of schools. Anyhow, those of our readers who can spare time to visit the two shows at South Kensington will well to avail themselves of the opportunity, for they assuredly come away with the satisfaction that they have learnt something to their advantage. Art amongst photographers is none too prominent.

* * *

During the Exposure. In a lecture delivered before the Photographic Association of Wisconsin on the "Use and Care of Photographic Lenses," which was reprinted in our last issue, Mr. L. F. Deardoff describes what he terms a "new" invention of his in photographic lenses. The new (?) invention consists in means of altering the focus of the lense during the exposure of the picture so as to obtain a certain amount "diffusion of focus" in the image. This the lecturer explains about by altering the distance between the components of the combination, causing them to advance or recede from one another, and thereby lengthening or shortening its focus while the picture is being exposed. Now his idea of obtaining the so-called diffusion of focus is not quite so new as Mr. Deardoff seems to imagine. As a matter of fact, it is nearly as old as photography itself. Our older readers will remember that in the year 1866, at the annual meeting of the British Association, and a little later on at the London Photographic Society (now the Royal), the late Mr. Antoine Claudet, then in business in Regent Street, described a means of getting a diffused focus of the image in precisely the same way as by the new (?) method of Mr. Deardoff. But the idea was not new then as Mr. Claudet surmised because it had been applied by the late Rev. J. B. Reade in 1851. At the time Mr. Claudet brought the subject forward there was considerable discussion on its merits—pro and con—as will be seen by reference to our volume for 1866. Claudet's method was brought forward specially with reference to portraiture, but it did not meet with much favour in practice, for in the September of that year the late Mr. J. H. Dallmeyer patented, and shortly after issued, his patent portrait lens by which any amount of spherical aberration could be introduced at will by separating, more or less, the components of the back combination of the instrument. This lens is at the time the one most in general use amongst the highest class portraitist. At the present time it is a little difficult to see how Claudet's arrangement or Mr. Deardoff's which is the same—could be applied in practice. At the time it was introduced the wet collodion process was in vogue, and the exposures in the studio ranged from anything between ten or fifteen seconds to a minute or more; then there was ample time for the alteration of the focus of the lens. Now with the brief exposures required with gelatine plates the conditions are quite different, and one can hardly conceive how the Claudet arrangement could be efficiently applied in practice.

* * *

Weather forecast. Many a photographer must have mentally exclaimed, as he hesitated about starting from home with his camera on account of the doubtful look of the sky, "Oh, if those newspaper forecasts could only be trusted, how valuable they would be!" He knows that they are right sometimes; as a matter of fact, they are right nearly nine times out of ten. But that is not enough. If you have a servant who is generally trustworthy, but indulges in a mendacious statement every tenth time he opens his mouth, you naturally hesitate to give credence to anything he

says. So it is with these forecasts; they may be right, but at the same time on one particular occasion the temptation to lie will be too strong for it, and the forecast leads you astray. It has long been known that the weather bureau of New York is much more trustworthy than ours; but this is not due to any greater virtue on the part of the officials, but is merely the accident of geographical position. For some reason best known to Dame Nature, the various changes in the meteorological conditions which we call "weather," travel over the surface of the earth, from west to east. New York has to its westward an enormous continent, and the wires bring from very distant places warnings of what is coming along in the neighbourhood of the clouds. And the message travels so much faster than the storm king that news of his majesty's approach reaches New York many hours before the rustle of his presence becomes evident. But our little country is flanked by a big ocean, upon the surface of which it would be quite futile to attempt to erect telegraph posts. Hence our meteorologists have been handicapped by no fault of their own, and we can only wonder that their forecasts have been as accurate as they are. But now a new day is dawning for the weather prophet, for the wireless telegraphic system makes it possible to receive details concerning the weather from the very middle of the Atlantic. Some time since a committee of scientific experts endeavoured to prevail upon the British Government to test "the efficacy of wireless telegraphy in giving advance information of the condition of the weather over the Atlantic." Of course, the Government took no notice; they are far too busy over party squabbles to bother about such a trivial thing. It was left to the Press to take the matter up, and the "Daily Telegraph" has had the enterprise to become the pioneer of the new system. By arrangement with the Marconi Company and with the Atlantic Steamship Companies, messages are to be sent daily to Fleet Street from ships a thousand miles away. Meteorologists will, by this means, learn the state of the barometer, the thermometer, the description of weather, the state of the sea, and other oceanic particulars likely to affect the weather which is on its way to our shores. With this new and potent addition to their present resources, the Meteorological Office ought to be able to give us most reliable information as to coming events, and not among the least grateful to the "Daily Telegraph" for its public spirited action will be our photographic friends, whose work is so much affected in various ways by climatic conditions.

* * *

On the Cheap.

The men who have the merit of bringing the halftone block to its present forward position have it on their conscience that they have been the means of foisting upon public attention a huge amount of mediocre illustrated literary matter. For a long time these blocks could not be printed so as to make a presentable appearance, except at huge expenditure on account of superfine paper and ink. But now these difficulties have been overcome, and the blocks are thrown at us from every direction. As a case in point we cite a certain small journal with a big title which has been sent to us from the Midlands, a perusal of which has occasioned us both amusement and instruction; we have gained the first from a study of the pictures, and the second from reading a notification on the front page which ingenuously shows how cheaply a publication of this sort can be run. The matter is of interest to photographers, because a weekly photographic competition forms part of the scheme, and those who are in the habit of sending pictures broadcast to publishers should be warned that care is necessary in fully understanding the conditions upon which those prints are

received. The notice referred to we will take the liberty of reproducing in condensed form, but for obvious reasons we do not give any names. The proprietors offer a prize of half a guinea for the best photograph sent in, and it must be the work of an amateur. Possibly the proprietors are aware that professionals would not care to compete, especially when they note the concluding paragraph of the advertisement, to which we shall presently come. A similar prize is offered for the best drawing; another half guinea for the best report of a sermon (500 words); and still another for the best original article, short story, or essay not exceeding 1,000 words! It is said that the most important part of a lady's letter is often to be found in the postscript, and this is certainly the case in the present instance, if we regard the concluding paragraph of the notice as such. We give it in its entirety:—"All photographs, drawings, and literary contributions sent in become the property of the proprietors, who reserve the right to reproduce the same." That means in plain words that, quite irrespective of any prize or other remuneration, the proprietors claim as their own any photograph or literary matter sent to them. We do not think that they will get many persons to contribute on these "heads I win, tails you lose terms," and from a general survey of the publication—which has been in existence for more than three years—we gather that most of the pictures are veiled advertisements, which, of course, are paid for in another way. Another point we note is that, in the allocation of these so-called prizes, the insignificant half-guinea is generally split so as to be divided between two competitors. Now let us see how this scheme works out for the proprietors of the publication. For an expenditure of only two guineas they get two original photographs, two original drawings, two reports of sermons (filling a column of space) and two stories, or articles, filling two columns. Those may be regarded as their legitimate toll on the credulity of their patrons. But beyond this two guineas' worth of literary and pictorial matter, they have all the stuff that is sent in which does not gain a prize. Possibly most of it is only fit for the waste paper basket, but this does for "padding," and this is quite evidently its fate in the case before us.

Newspaper Science.

The mistakes made by the journalistic scribe when he endeavours to soar beyond the limits of "the daily round, the common task," are not quite so absurd as they used to be before the amateur photographic boom. For the camera has brought with it a little chemical, optical, and other smatterings of knowledge, and has done good service in teaching people how to think out many a little problem. But even now, when there is so little mystery about the camera and its belongings, we find the most ignorant statements made in print by those who should know better. A writer in "Household Words" lately tried to impress his readers by stating that every time they took a photograph, or had their portrait taken, they were brought into intimate association with the explosive called "gun-cotton," because the apparently harmless dry plate had a coating of collodion, which was simply gun-cotton in solution! Next, please. An article recently appeared in "Answers" with the heading, "Taking Microbes' Photographs," and for utter imbecility we think it would take first prize. This is how it is done:—"The living germs to be pictured are put in a lantern slide (sic) in blood, or water, or other suitable medium, and projected on a screen, just as they might be by a physician giving a lecture, and showing to the class the actual living germ and its habits." We are next informed that while this sanguinary exhibition is going on a cinematographic film is taken of it, "the resulting total magnification being six millicm. Magnified to the

extent named, the germs of all diseases . . . are seen born, moving about, growing, giving birth to other germs, and dying, just as they do in real life." The idea of a dying just as it does in real life is an Irish bull of the best breed, and is only equalled by the supposition that blood is a suitable medium for the lodging of microbes, whilst their images are projected on a screen to be photographed at cinematograph speed. Some of the "photographic notes" contributed to provincial journals will raise many a hearty laugh if they were only published in the columns of one of the so-called "comic" papers. We are told in one of these gems of scientific accuracy that hypo is so cheap now that it pays to make up a quantity of solution, but that the mixture should be heated with hot water. It is a mistake to use cold water, for the temperature of the solution falls to such an extent that it is very slow and unsatisfactory." The writer seems to be under the impression that the fall of temperature accompanies dissolution of hypo crystals persists, and that a solution made with cold water will for ever hover about the freezing point. What an extremely useful salt it would be this hot weather if such were the case. One example of newspaper science is afforded by an evening paper, which lately gravely told its readers that dealers in spurious "antique" furniture were breeding worms in the order that the chairs and tables might receive the mark of age. But he did not stop here. He went on thusly:—"If the worms were allowed to eat too freely of the table leg, it would become unable to bear the weight imposed upon it." So the enterprising dealer employs X-rays to kill them in their holes. We are glad to hear about this, for hitherto we have not regarded the dealer as a man at his true value. Next time we traverse Tottenham Court Road we shall raise our hat at every man we pass, for we shall remember that the seller of tables and chairs is also a man of scientific attainments.

THE OPTICAL CONSTRUCTION OF MODERN CAMERAS.

PHOTOGRAPHIC lenses have reached a high state of perfection, but it is a curious fact that the construction of cameras, optically considered, cannot, as a rule, be equally satisfactory. A good deal of attention has been devoted to the provision of mechanical devices for keeping the plate vertical, by means of the swing-back, plumb-line, spirit-level, but it appears to have been largely overlooked that the position of the lens is at least equally important. It is an indispensable condition, if equality of definition and a truthful representation of the object photographed are desired, that the axis of the lens should be perpendicular to the plane of the image. In the majority of modern stand cameras this requirement is very far from being met. To take a few typical examples, there is a type of camera in which the front slides loosely on brass guides, in the baseboard or extension frame, and is clamped tightly in position by milled screws at the top, or in some cases the sides. It is evident at glance that the squareness of the front in relation to the plate depends greatly on the judgment of the operator, and that the chances of its not being straight are numerous. It must be remembered, too, that quite a slight deviation in the position of the front will throw the lens seriously out of centre. In some of the more recent patterns of cameras, the front is hinged to the extension frame, which at any rate disposes of lateral movement. The swing front, however, which usually accompanies this arrangement, makes it a matter of great uncertainty whether the lens is axially perpendicular, unless spirit levels are used on both the front and back.

There are many photographers who seem to hold the notion that so long as the back of the camera is carefully levelled, the position of the lens does not much matter. This is quite a delusion, and, as a little reflection will show, self-contradictory. It is true that, in architectural photography, it is often necessary and permissible to tilt the camera, and therefore the lens, in order to include elevated portions of the picture. This is, however, an exceptional means of meeting a special difficulty, rather than a plan to be deliberately pursued. Uniform definition has generally to be secured by stopping down, and the lens axis is commonly at right angles to the plane of the object, although not perpendicular.

The demand for portability and lightness has had a great deal to do with the present unscientific methods of camera construction. The old box-form apparatus of the prototype, with its sliding body serving to keep the lens perfectly square and parallel to the front, comes infinitely nearer to satisfying the demands of the optician than most of the elaborate contrivances now designed. It would seem to be preferable, on constructional grounds, that the front of the camera should be rigid and fixed, and simply the usual slide for the rising and falling movement. All other adjustments should then be arranged at the back, including focussing. The ordinary form of movable back, which slides along the baseboard, is often difficult to get level; a rackwork arrangement for securing any degree of extension would certainly be more desirable. The hand-camera worker who uses a fixed-focus apparatus has an advantage in this respect, for the lens is mostly mounted with great nicety. Even in many of the focussing cameras the optical arrangements leave little to be desired, although it must be admitted that in some of the cheaper varieties there is room for improvement. As much as can hardly be said of certain makes of folding hand-cameras, which are so designed that if the lens is ever slightly square to the plate it is more by a happy accident than otherwise. It may be said, as a rule, that the more intricate and delicate the apparatus, the greater possibility there is that the optical arrangements are questionable. This is not always an inherent defect in the instrument itself, being frequently developed by strain, acting on one part more than the rest. And this introduces another important question. A camera, no matter how perfect or strong it may have been originally, tends, like everything else terrestrial, to deteriorate with time and use. If this is not only a consideration of a little less polish, or a few more scratches and dents here and there, it would be of small consequence, but, unfortunately, it sometimes takes the form of warping or twisting. Still more unluckily, this objectionable trait often chooses to manifest itself in just the very arts where it is least desired, namely, in one or other of the camera movements. This is a frequent source of imperfect optical adjustment, in many cases entirely overlooked, until the erratic performance of the lens, in connection with some important work, possibly draws attention to it.

While dealing with this subject, there is another point which requires notice; it concerns the lens flange. In some cases, where the worker screws this on himself, it is not at all uncommon to see it attached in a most slovenly fashion, with screws of different sizes, or even, be it whispered sadly, with tacks. Now, it will not be attempted to deny that, however inartistic or slipshod such methods of workmanship may be, they serve their destined purpose if the flange is properly fastened. As might be expected, however, one deed of carelessness leads to another, and will perhaps happen that a rough edge left from hacking out the circular hole in the front with a blunt pen-knife, a small lump of grit on the surface, or some similar cause, will result in the flange not lying flat. As a conse-

quence, the lens is doomed to a permanent crookedness, which, however slight it may be, is still undesirable. It is occasionally noticed that the screw threads of the lens and flange are not axial to the mount, so that the objectives does not screw on straight. This, however, is a matter of rare occurrence, and should certainly involve the return of the lens. Nothing has been said as to the necessity of exact register between the focussing screen and the plate. This is a commonplace which is universally taken for granted. Whether it is always secured in practice is another thing, not undeserving of inquiry. These may seem matters of little moment to the easy-going photographer, but it is on the aggregate of such trifles that good work really depends. It is, at all events, only reasonable that the worker who is willing to pay for an expensive, highly-finished lens, the product of consummate optical skill and calculation, should see that he does not negate half the benefits of his purchase through faulty and inaccurate adjustment. The time spent in making a few simple tests and experiments, which will perhaps enable the mischief to be remedied or proper precautions to be taken against its occurrence, cannot possibly be wasted, and may be amply repaid.

ON THINGS IN GENERAL.

ANOTHER Convention meeting has come and gone, and I expect every conventioner is looking forward to the next on account of its venue, as the lawyers phrase it. It would be invidious to draw distinctions, especially after the highly successful Derby visit, where every one on the spot did his very best to make the meeting the success it was. The arrangements for excursions were excellent, and the exertions of the local committee and helpers must have been exhausting, so early and late and indefatigably did they work; and the more praiseworthy such efforts are, seeing that it was a case of "virtue being its own reward," unless, indeed, the hearty and sincere thanks of every visitor can be counted as such. Even the weather arrangements were perfect, the wetting which a small section of the Tuesday excursionists to Dovedale experienced being partially their own fault, the beauties of the neighbourhood chaining them to the spot for too long a time. There was, perhaps, one "fly in the pot of honey," several of those who went to Haddon Hall and Chatsworth declaring that the order of going should have been reversed, and made as just written. But I shrewdly suspect this was done on purpose. We read of Alcibiades cutting off the tail of his favourite dog, and replying, when he was asked the reason for such a deed, that the citizens were sure to invent something worse to tax him with unless he gave them what we moderns would term concrete cause. So the Derbyites, knowing how they had engineered success, decided to give occasion for a mild grumble lest a more serious fault were invented! And now, "Le Roi est mort, vive le Roi." Will there not be a crowd at Dublin if the survivors alone of the last visit—with recollections of its splendid hospitality, its glorious weather, and the beauty spots so easy of access around it—decide to repeat their experience?

Of course, so much of success with these gatherings depends upon the weather conditions that obtain. We can scarcely hope that the changes in the Meteorological Office foreshadowed in a recent issue of this journal will be carried out within a year's time, far less that we shall then have reliable vaticinations to inform us whether it is needful to take our umbrellas and overcoats on each journey or leave them at home. We shall still continue to bring them home (I rightly use this word, for the Dublinites did make us feel at home) without using them, and leave them behind when we should cherish them as a best friend. That is the natural way of things which Fate will not permit

to be tampered with. I recollect a case where a vain mortal did attempt such toying. We were eighty in number, and on such a day as the Dovedale day, we climbed a stiff hill and left everything portable at the hotel in our rear, all except this solitary victim. A thunderstorm came on; all but he took refuge like Agag, he meanwhile perambulating in front of our sheltering cave protected by his best gingham and a long waterproof coat, and expatiating the while to us poor-prisoners on the beauty of the storm and the glorious surroundings. He was so proud of this that he would not take his waterproof off when the downpour ceased, and he kept it on for the rest of the evening as proof of his superior insight. Then Fate stepped in and had a long innings. Of course, he caught a chill, and he was in bed with lung trouble for two months after. There is a moral somewhere here; perhaps it will be discerned before the Dublin meeting arrives.

Speaking of the weather, is there any one who can explain the reason why the public still hold fast to the faith that a "bright sunshiny day" is an essential for successful portrait taking? Of course, we all know that in the pre-collodion days, the very beginning of portrait-taking by light, the sitter had to sit for about twenty minutes in the broiling sun, and was supposed not to blink. But though all that is changed and become ancient history to the initiated, the tradition still remains. So many people will insist upon waiting for a day with plenty of sun to have their photographs taken, the photographer's assertion to the contrary being brushed aside as mere banter, amusing, but a figment. The incident recently quoted of the sitter who in the middle of one of these ancient exposures suddenly called out to the photographer to stop, as he had spoiled the picture by winking, may be looked upon as an exaggeration. But an experience of my own many years ago would bear out its probable accuracy. A lady wished to be taken late on a very, very dull day. I asked her to defer the sitting; but she preferred not, and could "stand any length of time." I told her she would have to sit for two minutes. She preferred to stand. She did not say "she could do it on her head," but was equally positive. I used a head-rest, and took off the lens-cap. Ninety seconds had gone, when a doleful cry of "Oh, I've winked!" was uttered. I capped the lens immediately and told her that would do; and it did. The negative is in existence to this day, though the incident happened close on forty years ago.

The newspaper correspondent and the cinematographer are famous, not to say notorious, for enterprise. Nothing whatsoever is sacred to them. Yet there is a line that public feeling will not permit them to over step. Who can forget the terrible disaster of a few years ago on the Thames, where a cinematograph happened to be working when a sudden wave, through the launching of a vessel, caused the immersion of hundreds of unfortunate onlookers, whose drowning struggles were depicted by the lens on a thousand feet of film? The terrible pictures were exhibited—at the Alhambra, I believe—but withdrawn in deference to the public sense of horror. But such a ruthless attempt to make money pales into insignificance before the promise of a ghastly exhibition actually arranged for in China. In the "Notes and News" for July 22 will be seen a paragraph stating, on the authority of a Hong Kong newspaper, that executions are being delayed in Canton till the arrival from America of a cinematographer and his apparatus, who will proceed to make records of the horrible sight for exhibiting at the St. Louis Exhibition. Surely the whole American nation will protest against such an outrage! True, the report comes from Hong Kong, which probably King David had in his mind when he said "all men are liars." I shall be reminded that he said it in his "haste," but he might have taken his time when Hong Kong newsmongers were in question, and the innate probability of the story will be granted

when I say that, by a singular coincidence, a friend sent me the same morning I read the paragraph in a newspaper series of photographs of an execution of Boxers in China, showing from the procession of the criminal wretches, through securing of the men in position, the descent of the lethal gas, the road strewn with headless corpses, down to the carrying of the basket of heads to the accompaniment of the sardonic of an official as from the overlaid basket there accidentally dropped one single head on to the ground. The set was a masterpiece in itself. What this threatened cinematograph show would be surpasses in fearful horror anything conceivable. Human rebels at the idea; it will never be exhibited, even if taken.

The article in these pages, "The Present State of the Photographic Labour Market," in combination with that entitled "Photography as a Profession in the United States," and quoted data from German sources of the rates of pay to photographers in that country, depict a truly woeful state of affairs. And the worst of it is that there appears to be no probability of a change for the better. Even among principals, it is doubtful whether any but a few of those who do the highest and dearest work—cabinets four guineas a dozen, and those catering for the multitude at a shilling a dozen—making a "living wage," or even that. But can it be won at? The introduction of the dry plate sounded the death-knell of the average professional, for any one with a month or more of practice can now take a decent photograph, while even a layman would have to serve a long apprenticeship before becoming expert enough to earn a wage. Certainly his wage would not pass that of a photographer's assistant; but that is a different matter. The only consolation to be offered is that there are assistants and assistants, and no pity can be felt for a man who enters a calling requiring no more experience than a rag-picker and whines when he gets rag-pickers' wages. For there are master rag-pickers who make big fortunes—at least, when they are called chiffonniers.

Bravo! your Honour Judge Sir Horatio Lloyd, for assisting the camera-carrier, be he amateur or professional, to take his photographic impedimenta as personal luggage. Every hand is usually raised against the railway company, because it has neither a soul to be damned nor a body to be kicked, but simply because, in its anxiety for dividends, it loses an opportunity of "taking it out" of any traveller. Decisions of many judges of the land have been their claws to be cut; yet they still can scratch very hard on occasion, and they do scratch. What is the result? The honest dictates of honesty are set aside when railway companies are in question. There are few people who do not say they have been "done" by them at one time or another, and consequently, feel justified in doing what with an individual would be characterised as a mean, if not dishonest, act. Perhaps the lines are not wholly to blame, for it is undoubted that they are so continually subject to fudged claims and false applications for damages and loss that they get into a way of considering every one to be a rogue till he is proved to be honest.

FREE LANCET.

MR. CLEMENT B. VANCE, of the Burnaby Pharmacy, Greystock, Wicklow, Ireland, writes:—"This being holiday time, those of your readers who intend visiting 'The Garden of Ireland' may be interested to know that a well-equipped dark room is now available at above address, opposite the railway station; and that plates, papers, etc., can also be had."

MR. ERNEST F. BAUM, of Keble College, Oxford, whose name appears in class 1 of the award of honours issued by the examination in the Final Classical School, is a son of Mr. Franz Baum, photographer, of Manchester. He was born at Bowdon in 1881, and has a distinguished career at Manchester Grammar School, where he was twice Shakespeare scholar.

THE COMPOSITE PRINT IN THREE-COLOUR PHOTOGRAPHY.

HOWEVER great precautions be taken in the adjusting of colour filters to plates, and of both to physical theoretical requirements, the chances of error are still very large in staining the films, which by superimposition are to give the rendering of the original in natural colours.

If commercial three-colour photographers knew to what extent the work of their re-etchers could be minimised by accurate adjustment of colour filters to plates, they would not use one make of filters with another make of screens, nor try a new set of plates and declare them inappropriate without first testing them with filters specially adapted to that particular emulsion.

The use of panchromatic plates instead of ordinary, yellow-green, and red-sensitive plates has one very decided advantage—that if each batch of plates vary, only one has to be tested for colour-sensitiveness instead of two—the yellow-green and red-sensitive plates.

Commercial plates should, of course, never vary enough to occasion an alteration in the filters, and it is therefore pretty safe to employ dry filters. But the point to which we would draw special attention is this. The three-colour work the printer is often, and generally, far nearer to nature than that of the amateur, i.e., the man who makes transparencies by superimposing films. Now, why is this?

The answer is not far to seek. The printer has retouchers and re-etchers who supply to the printing blocks such modification as their deficiencies may necessitate. But the amateur who prints his films and stains them, is more or less at the mercy of the scientific working of his screens, dyes, and plates. Etching is for him a difficult matter, and unless his films are dyed to the correct depth and with the right dyes, some error is fairly certain to creep in which will render the composite print or transparency more or less disappointing.

It is the duty of the plate-maker to supply a fairly perfect panchromatic plate, and to recommend or supply to the users the suitable screens or the materials for making the same. Beyond this, however, the photographer has to look to himself, and hence some work has yet to be done to clear up all doubts as to the adjustment of staining-dyes to colour filters.

The dyes in common use for staining are, it is needless to say, bluish-green, pink, and yellow in colour, respectively. But such circumstances as the alteration of the blue dye when, for example, a red filter lighter than usual is used owing to deficiency in red-sensitiveness of the plates, must necessarily influence the preparation of the staining solutions.

It is interesting, as well as confusing, to refer to the textbooks on colour photography, and observe their advice with regard to staining. Thus Hübl, in the 1902 edition of his *Dreifarbentypographie*, suggests on one page the use of neutral erythrosin solution, acid naphthol yellow solution, and acid fast bluish-green solution for the pink, yellow, and blue prints respectively. Two pages further on he gives in full the dyes recommended by Lumière, as being erythrosin, diamine blue, erysphenin. Two different results will obviously be given with the above combination. In our own practice we have found that a mixture of methyl blue and naphthol green, erythrosin, and auracin G give very satisfactory results, and although we would not for a moment suggest the substitution of dyes in possibly more common use, yet some remarks respecting these colouring matters may be of service to those who are not obtaining the most satisfactory results with those they are at present using.

Assuming the colour filters to be correct, the yellow "printer" will have recorded the violets, blues, and blue-greens, the former and latter in half-tone, i.e., not so deeply as the blues; the pink printer will have recorded the blues, bluish-greens, greens, and yellows, and a little of the orange; the blue printer will have

recorded the yellowish-greens, yellows, and reds. These negatives being printed from, the resulting positives must be stained in colours approximately complementary to the colours of the filters respectively. Thus, if we represent the total colour in the spectrum by x , and the light passed by the blue filter as a , the transmitted colour of the yellow film must be $x-a$; in other words, the colours of the films should (approximately) be the same as the absorptions of the respective filters.

A great difficulty exists in putting the staining process on a scientific basis. Theoretically, the films should never vary in thickness, the dyes never in concentration nor temperature, and the methods of staining up should be scientifically uniform. That this is impossible is obvious to the merest tyro in colour photography; and hence the non-conformity to scientific rules leads to incorrect results, the incorrectness of which is put down to personal equation.

When a panchromatic plate is used of such even colour-sensitiveness that theoretically correct colour filters are available, then the combination of any colour filter with its corresponding stained film should not permit the passage of any rays when spectroscopically examined. This is rarely the case in practice, and the following example will clearly indicate the reason why. A certain brand of plate is deficient in green and red sensitiveness; that is to say, its sensitiveness to blue is greater proportionally than it should be. Hence, not such a dark blue filter as usual is necessary to cut off the action of the yellows and reds in the blue exposure; this filter is therefore "adapted" to the plate so as to save time in exposure. But being lighter than theory requires, it emits the passage of "foreign" rays, and therefore is not strictly complementary in colour to its yellow-stained fellow.

The following are the dyeing solutions to which we have already referred:—The yellow staining bath is made up by digesting auracin G with one hundred times its quantity of water at 200 deg. Fahr. for half an hour, then cooling and filtering it. The pink bath is made with erythrosin, one part, in one hundred parts of spirit. The blue bath is prepared by mixing two parts of methyl blue, one-third part of naphthol green, and one hundred parts of water. These are stock solutions only, and must be mixed further with water for use.

It is difficult to get the gradation very well rendered when using bichromated film, but it will be found that the more dilute the staining bath, the better the gradation. Thus two or three hours may be given with advantage for staining, and we certainly believe in letting the films dry after development, and putting them dry into the staining solutions.

If the blue staining bath be found to produce streaks, add a little thin fish glue to it, and stir it up well. Methyl blue does not make a good keeping solution, and it is therefore best made up soon before use.

The auracin will be found to give a slightly more orange yellow than naphthol yellow or crysphenin, the colour imparted being distinctly primrose, and similar to that of $\lambda=5896$.

The question of fluorescence is one which deserves consideration, and owing to the peculiar behaviour of fluorescent bodies and their variation in properties with different colours, it is perhaps not advisable to employ such dyes as erythrosin and auracin for staining purposes. There is, however, no definite data to go upon in this direction, as the subject of fluorescence itself is not a very familiar one to scientists at the present day.

T. THORNE BAKER, F.C.S.

At the Newbury Photographic Exhibition, to be held next month, an interesting series of balloon pictures, the work of the Rev. J. M. Bacon, the famous aeronaut, will be on view. Miss Bacon is also exhibiting and is lecturing during the exhibition. Those who have not yet received schedules would do well to apply to the Hon. Secretary, E. J. Forster, Guildhall Club, Newbury, as entries close on September 1st.

THE APPLICATION OF ALLOTROPIC SILVER FOR THE PREPARATION OF CONDUCTING FIBRES.

[From the "Physical Review."]

A NUMBER of articles discussing allotropic modifications of silver have appeared in the various journals since 1889. These articles treat rather of the methods of preparation and physical condition of the different allotropic modifications, than of any application of them. A complete list of references is given by Barus and Schneider.¹ Three forms of allotropic silver are described, all of which have certain properties common to themselves and which distinguish them from ordinary silver. When a suspension or emulsion of any of these forms of allotropic silver is spread over paper and dried, the particles are left in optical contact and thus form an apparently continuous film. Treatment with halogens produces brilliant interference colour effects. All the forms are very readily changed to an impalpable powder. Treatment with acids instantly changes all forms to ordinary silver, with apparently no chemical action. No gas is evolved. It is the purpose of this article to give a simple and efficient means for the preparation of conducting fibres; whether they be used for suspension, as in the quadrant electrometer, or otherwise; and whether the fibre material be quartz or any other suitable substance. The allotropic silver used was prepared according to the process described by Carey Lea.²

A mixture of 200 c.c. of a 30 per cent. solution of ferrous sulphate and 280 c.c. of a 40 per cent. solution of sodium citrate was treated with a 10 per cent. solution of sodium hydroxide, just till no permanent precipitate formed. This was then mixed with 200 c.c. of a 10 per cent. silver nitrate solution stirred thoroughly, allowed to settle and the liquid decanted. The precipitated allotropic silver was treated with about 200 c.c. of distilled water, which dissolved a part of it, and was again precipitated by treatment with a saturated solution of ammonium nitrate. This process was repeated three times, and the final precipitate filtered with suction and washed with 95 per cent. alcohol. The product was transferred, in the form of a brown mud, to a bottle and kept covered with alcohol. The allotropic silver was used for the experiments as an emulsion in alcohol, alcohol being used rather than water as it dries more quickly, and thus the dry film of allotropic silver can be obtained in a very few minutes after spreading the emulsion. This emulsion spread on any surface and dried gave a copper-coloured film. When dried on a glass plate and viewed through the glass, it gave a good mirror, but of a dark colour. When these films were treated with gaseous hydrochloric acid they were immediately changed to ordinary silver and presented a dull silvery appearance. The films are changed to a bright silver surface by slight friction. It was the action of the gaseous hydrochloric acid, which suggested the investigation.

Glass plates were painted with the emulsion and dried. The conductivity of the films in this condition was found to be very poor. It was tested by placing the terminals of an ordinary dry battery upon the films with an ammeter in circuit. The electro-motive force of the battery was about two volts, and the terminals were placed eight or ten centimetres apart. The films were then treated with gaseous hydrochloric acid by blowing through an arrangement like a reversed wash-bottle, the bottle containing a little strong hydrochloric acid. By this means a stream of gaseous hydrochloric acid was very readily directed upon the allotropic silver films, thus changing them to sheets of ordinary silver. These films were then tried with a battery as before, and found to be excellent conductors. The use of the silver was then tried on the quartz film of a quadrant electrometer as follows:—The quartz fibre, suspending the aluminium needle between the hollow quadrants, was hung from a hook which was thoroughly insulated with hard rubber. The whole

was enclosed in a copper case to prevent disturbance by currents, and a beam of light reflected through a glass window in the copper case, from a mirror fixed on the needle, served as a pointer on a transparent scale arranged at the proper distance. The instrument having been adjusted, experiments were tried to see how quickly the needle responded on being charged. It was found to respond instantaneously. Various tests on the electrometer with the fibre prepared are above stated were perfectly satisfactory.

CONCLUSIONS.

The dried films of allotropic silver although poor conductors become very good conductors on treatment with gaseous hydrochloric acid. The emulsion can be used admirably for the preparation of conducting fibres; and can be applied to the most delicate apparatus in a very few minutes, without danger of injury. The above work was done in the physics laboratory of Brown University. In closing, the writer wishes to express thanks to Professor Carl Barus, for his valuable instruction and friendly aid.

N. A. DUBOIS

SUPPLEMENTARY SENSITISERS.

[Translated from the "Zeitschrift für Wissenschaftliche Photographie."]

H. W. VOGEL at an early date discovered by experience that unfavourable properties of cyanine for the preparation of sensitive plates could be corrected, if a suitable quantity of quinolin-red be added to it. His azaline is such a mixture.

If we make a spectroscopic examination of plates prepared with an ammoniacal solution of cyanine (1 part cyanine, 6 parts water, 4,000 parts alcohol, 10 parts ammonia), and compare them with plates dipped in azaline (1 part cyanine, 10 parts quinolin-red, 10,000 parts water + alcohol, 10 parts ammonia), we find in the latter, besides the action of the cyanine sensitive band in the green due to the quinolin-red sensitiser, a considerable increment of speed, and less disposition to spoil than when cyanine alone is used. Eosine in presence of cyanine acts similarly.

Subsequently I showed that the powerful screening action of the large addition of quinolin-red might be reduced by using less highly coloured sensitiser obtained by precipitating a large part of the original quantity of quinolin-red with glycine-r ("Atelier des Photographen," 1901, No. 1.) The plates thus prepared are much clearer than azaline plates, and possess keeping quality, probably because of the reduced quantity of dye-stuff left after the good washing they receive. Similar results cannot be obtained by reducing the quantity of quinolin-red.

More recent observations have shown that the eosines and quinolin-red, as well as a few other dye-stuffs, which of themselves are not sensitisers, also have perceptible and great practical value with the isocyanines, as auxiliaries for colour sensitisation. For example, the action of quinolin-red with methyl-red nitrate (nitrate of the isocyanine from quinolin-methyl iodide and quinaldin-methyl iodide) is very remarkable. If a plate be stained with methyl-red nitrate (1 in 50,000), although it be dried quickly, a slight to medium amount of fog will appear. But if the bath be prepared with an addition of quinolin-red, or less effectively with erythrosine (1 part methyl-red nitrate, 4 parts quinolin-red, 400 parts alcohol, 50,000 parts water), after washing there will be no fog, and the plates will be of excellent colour, sensitiveness and keeping quality, even if dried slowly. The curve of sensitiveness will not have altered much, according to the absolute height of the maxima, but will appear to be more even, and the separate maxima will be less prominent. By substituting erythrosine for quinolin-red the same counteraction of fog is apparent, but the spectral band is less continuous.

Also with ethyl-red nitrate (nitrate of the isocyanine from quinoliniodethylate and quinaldiniodethylate) an exceptionally favourable action is observable, as the plates are free from fog

¹ Wied. Ann., XLVIII., p. 327, 1893.

² Ann. Jour. Sci., XXXVII., p. 476, 1892.

when slowly and unevenly dried. Quinolin-red works really well with orthochrom and König's pinachrom. These sensitisers, which otherwise show considerable tendency to fog most plates, are free from the fault if used with a corresponding amount of quinolin-red (1 to 5, or 1 to 6). The use of some other cyanines and isocyanines with very extensive sensitiveness for red, is rendered possible by addition of quinolin-red. For instance, the nitrate of ethylcyanine (quinolin-sepidin-ethylcyanine) has good red sensitiveness as far as 670, but a wide gap at 535 and the plates are very foggy and spotty, and striped. When used with quinolin-red exceptionally good panchromatic action, with perfect freedom from fog and good general sensitiveness, results. The following is a good formula:—

Ethylcyanine nitrate (1 to 1,000 water + alcohol)	10 c.c.
Quinolin-red (1 to 1,000 + alcohol)	50 c.c.
Water	500 c.c.

570 $\mu\mu$
Ammonia 3 c.c.
The colour sensitiveness is almost perfectly equal, and extends All the sensitisers of the class of the cyanines and isocyanines appear to be favourably affected by the action of quinolin-red, and thus we have the possibility of bringing into use other sensitisers from this class.

THE OPTICAL PROPERTIES OF DEVELOPED LIPPMANN EMULSIONS¹.

[Translated from the "Photographisches Wochenblatt."]

HERR KIRCHNER² gives an account concerning the occurrence of various different colours in developed Lippmann plates, in the exposure of which the formation of stationary waves was excluded.

Unfortunately Herr Kirchner only used pyrogallol, amidol, and metol for development. With less energetically acting hydroquinone (mixed with soda, sulphite, and bromide of potassium) a large number of pronounced colours are obtainable. Moreover, these colours are better, if grainless chloride, instead of bromide of silver be used. The production of definite colours can be reckoned upon so easily in advance that it is possible to use the process in practical photography.

If an exposed gelatine-chloride plate be placed in a very dilute hydroquinone developer, a pale yellow image appears first. By continuing the development, the colour successively changes to orange, brown, olive, and green. Long immersion in a specially dilute developer produces a vigorous, pure red. Pure black and blue-black are obtainable with amidol and metol. Pyrogallol occupies an exceptional position amongst developers, because under certain conditions an oxidation product of the same is obtained and deposited upon the reduced silver haloid, by which means the image may be stained brown.³ (As this oxidation product has a strong tanning action upon the gelatine, there are differences of expansion in the film at the exposed and unexposed parts.)

The following experiment⁴ should support the hypothesis that the various colours are dependent upon the size of the complex molecules of silver. If a small quantity of hydroquinone developer be added to a mixture of nitrate of silver and gelatine solution, there is no immediate perception of colour. The solution then turns yellow, brown-red, and finally quite opaque. If at each stage a small quantity be spread upon glass and allowed to set, these specimens remain unchanged. The first will be

perfectly transparent, the next yellow, the following brown-red, and finally we shall arrive at deep black by reflected light, and blue-black by transmitted light.⁵

I think it is probable that the chemical reaction is not actually slowed by the gelatine,⁶ but that the latter hinders the formation of the larger complex nascent silver molecules.⁷

In judging Kirchner's observations⁸, the circumstance is not unimportant, that silver haloid is not quite motionless in the sensitive film: that the sulphite added to the developer, the bromide of potassium, and especially the ammonia used by Kirchner, are solvents of bromide and chloride of silver. Moreover, the nascent metal liberated from the silver haloid may deposit itself, grain upon grain, and form larger aggregates. On the other hand, development of the unexposed parts of the film may thus be brought about. The pseudo-solarisation observed by Kirchner may be traced back to this.

DR. RAPHAEL E. LIESEGANG.

PRINTS FROM LEAVES.

[Reproduced by courtesy of the Editor of the "Pharmaceutical Journal."]

ONE of the earliest recorded photographic processes consisted in transferring to a prepared surface the outline and veins of a leaf. It was, of course, a primitive process, and the results could only have been striking to those as yet unfamiliar with the wonders of a new art, and because an improvement over anything of the kind yet produced.

Spirea Bumalda.

In 1839, at the exact time when an account of the Daguerrotype process was first published in France, an Englishman named Talbot read a paper on "Photogenic Drawings" before the Royal Society. A description of his method of procedure, with reproductions of a fern-leaf, will be found in Abney's well-known work on photography. An almost identical process, of which the illustrations are examples, is in fairly common use at the present day. No knowledge of photography is required beyond that of a process of toning necessary in order to render the prints

¹ I therefore assume that the same quantity of metallic silver can be at one time perfectly transparent and at another almost opaque.

⁸ R. E. Liesegang, *Camera Obscura*, p. 841.

permanent, and a few general directions may be of interest as much to the photographic reader as to the student of botany. It is of the first importance that the leaf should be suitable, but there should be no difficulty in selecting such throughout the summer season. The leaves should be as flat as possible, of medium density, and with veins conspicuous as white lines by transmitted light. Simple leaves, or those not much divided, are usually best. Good results are easily obtained from those of lilac, lily-of-the-valley, sycamore, horse-chestnut, and certain species of *Populus*, *Polygonum*, *Cratægus*, *Spiræa*, *Liriodendron*, *Aristolochia*, *Hydrangea*, *Adiantum*, etc.

The process is one of simple contact printing, and to carry it out the leaf is placed in an ordinary photographic printing-frame, supported on a clean glass plate. The material must be made use of while quite fresh, and it is often an advantage to press between sheets of blotting-paper, so as to flatten out and remove superfluous moisture. After preparing it, if necessary, in this way, the leaf is to be used as a negative, and printed

Populus Balsamifera.

from a few times in the usual way. The sensitive paper—ordinary gelatino-chloride printing-out paper answers well—is laid upon the smooth upper surface of the leaf, and the frame exposed to strong sunlight. When sufficiently exposed—that is, when all available detail has been obtained—the print is toned and mounted in the usual way.

A collection of such photographs may be utilised for teaching purposes, in order to illustrate the complexity of venation, the variety of general outline, the differences in margin and apex, and other features of the leaf. For example, leaves of, say, *Populus*, *Convallaria*, and *Adiantum* might be shown side by side, to impress upon the student the arrangement of veins characteristic of three different classes of plants. Examples of further applications will suggest themselves to those interested. Lantern-slides can be prepared in the same way, printing, of course, by artificial light. Lastly, a variation—perhaps an improvement—is gained by a double printing, either on plates or paper, so as to reverse the densities of the original print.

It is unfortunate that the application of this process is limited. Many leaves, such as the evergreen, are inconspicuously veined and of substantial texture, so that with these it is impossible to get good results; while, on the other hand, leaves are often too uniformly transparent, and thus present difficulties from lack of contrast.

BERTRAM COCKBURN, Ph.C.

THE LATE CAPTAIN NOBLE ("F.R.A.S.").

THERE was more than one member of the Royal Astronomical Society whom this name and style applied (writes "H. P. H." in "The Observatory"), but it was sufficiently distinctive to most of the Fellows who attend the meetings. They called to mind but one personality—a long, lean figure which met one with a warm handshake and followed up the greeting with a whisper of his latest good story or the exact humorous quotation applicable to the occasion. This Captain William Noble, F.R.A.S., whose loss many astronomical amateurs and professionals, now have reason to deplore.

He was not the Senior Fellow of the Society, but he was among the first ten, and had probably attended more meetings than any other. He was elected in June, 1855, and very shortly after began to take part in the proceedings of the society, for an account of an occultation of Mars communicated by him will be found in the "Monthly Notices" for 1857, and there are few volumes among those for many years afterwards which do not contain some contribution from his pen. He was an excellent observer of such small phenomena, inasmuch as he set down what he saw, and exactly what he saw, however apparently improbable and trivial it might seem at the time. There will be found, for instance, in the "Monthly Notices" a note by him to the effect that while observing the sun one day in a hazy sky, the focal length of the objective glass apparently shortened by 0.11 in., but when the haze cleared, the focus returned to its normal position—a remark which may not have had any immediate bearing, but was simply the expression of a well-observed fact, which may find an explanation hereafter. It is not quite certain when he began to interject in the discussions at the meetings those remarks which were so characteristic of him, for in the early years of his fellowship verbatim reports of the proceedings were made; but at the meeting on April 8, 1864, there was a discussion about the willow-leaf markings on the solar surface (a not unusual object of those days), and the account relates that Captain Noble said that or he thought he saw them, and "if I had been Archimedes or a patent shirt maker I should have cried 'Eureka'!"—which is just the kind of remark that he continued to make until the end of his life. No discussion was so serious but that Captain Noble could get up and make some little speech, possibly wholly irrelevant, but always amusing, and for this, if for no other reason, he will be missed at Burlington House.

But his remarks were not always irrelevant. Captain Noble was fearlessly outspoken on matters that he thought called for remedy, even to the verge of prejudice. Delayed publication of the "Monthly Notices" frequently induced him to make pertinent inquiry of the President. The supposed shortcomings of the "Nautical Almanac" under a former regime often led to his sarcastic comment; but his *l'œuvre* was the Solar Physics Committee and its work. One wonders why he was so bitter on the subject, for he was a man of discernment and could appreciate good work, even though it was not strictly *ultramarine*; but the fact seems to have been that about the year 1870 when the proposal was brought forward for the establishment of an observatory at South Kensington at the public expense, some popular opposition arose, and Captain Noble was the secretary of the Society for Opposing the Endowment of Research. The observatory was established, as everyone knows, and no doubt the society was disbanded; but its secretary, being a consistent man, continued his opposition. Each fortnight, for many years past, a long letter appeared in the "English Mechanic," over the signature "A Fellow of the Royal Astronomical Society," which it is an open secret was pseudonym for Captain Noble, often containing criticisms on the work of the Kensington Science Department, almost libellous; but those who knew the writer were aware that his "bark was worse than his bite."

Besides observations of the kind indicated above, occultations of stars

planets of sun spots, and other occasional phenomena which he communicated to the society, he made, but has not published, an excellent series of drawings of the surface of Jupiter, and his fortnightly letter the paper above mentioned showed how completely he kept himself informed of all that was going on in the science. In this letter he played the part of mentor to the many amateurs who are correspondents of the journal, and no doubt this, combined with his genial personality, caused him to be selected as the first President of the British Astronomical Association. He contributed sometimes to these pages, and the early days of "Knowledge" wrote for that magazine a series of papers called "Nights with a 3in. Telescope," which were afterwards published as a book. But astronomy was not his chief occupation. He lived the life of a country gentleman at Uckfield, in Sussex, where he was one of the best known and best liked men in the neighbourhood, and filled many of the parochial and public offices justly and ably. For forty-six years he sat as a magistrate at Uckfield Petty Sessions, and was Chairman of the Bench at the time of his death. For thirty-four years he presided over the meetings of the Uckfield Board of Guardians, and was elected chairman for the thirty-fifth time shortly before his death. He had a special distaste for tramps, against whom he waged bitter war; and if one were brought before him he would, if possible, a sentence involving stone breaking, for, said he, "It spoils the delicacy of their hands for picking pockets, which is their normal occupation"—a sensible point of view which was quite characteristic.

As to actual details of his life, Captain Noble was the eldest son of the late Mr. William Noble, of Berwick, and was born in London, 1828. He was educated privately, and served for a time in the Rifle Brigade, where he reached the rank always associated with his name. In 1851 he married Emily Charlotte, the only child of Mr. Edward Irving, and had four sons. One, who survives, has lived abroad for many years; the others predeceased their father, the youngest leaving a widow and two daughters. Mrs. Noble died a few years ago. Captain Noble was elected to the Council of the Royal Astronomical Society in 1866, and sat at the board almost continuously after that date. It may be mentioned, as illustrative of one phase of his character, that he refused for many years to be a member of the R.A.S. Club, though invited to do so, for he seemed to think that this was a clique inimical to the best interests of the society, but quite lately withdrew his opposition and joined the circle. The immediate cause of his death will be gathered from the following extract from a letter received by the writer of this notice from him on April 18 last:—

"... I have been somewhat seriously ill. At the beginning of the year, thanks to our infernal climate, I got a chill, which brought on kidney and bladder troubles, and I am still under medical (and surgical) treatment. My chief present grievance is my inability to eat, and I am as weak as a rat. I am ordinarily a great walker, but a mile is quite as much as, or more than, I can manage at present. I do hope that I shall pick up enough to be present at the May meeting of the R.A.S., but, like the man you have heard me quote before who went for four ounces of mixed tea, 'I hope for the best and am prepared for the worst.'"

He did not appear at the May meeting, and grew rapidly worse during May and June, suffering a good deal of pain at the end, but bore up in the most wonderful way, and tried to keep up all his pursuits till the last. The end came on Saturday, July 9.

An admirable photograph of Mme. Sarah Bernhardt appears in a French illustrated magazine. It represents her among the rocks at Belle-Isle, communing with the Ocean, and probably adorning it, after the manner of Byron, to "roll on." To reach the rocky altitude the actress must have had a stiff climb; yet she is wearing a pair of fashionable, high-heeled shoes, totally unsuited for climbing. This seemed odd until a keen observer discovered in a corner of the photograph another pair of shoes, admirably business-like among the rocks, but not picturesque enough for communing with the ocean. They had served their purpose; they had borne the burden and heat of the day; and now their rivals had the glory. But the camera had done them justice after all, and as the keen observer remarks, they will go down to posterity as proofs of Mme. Bernhardt's artistic care even for the humblest details.

THE SCIENTIFIC METHOD.

We observe that an organisation is being formed, under the name of the British Science Guild, with the object of insisting on the importance of applying scientific methods to every branch of the affairs of the nation. The movement has grown out of a suggestion made by Sir Norman Lockyer last year in his address as President of the British Association. The Organising Committee has issued a memorandum describing briefly the objects, methods, and proposed organisation of the guild. The objects are stated to be as follow:—

- (1) To bring together as members of the guild all those throughout the Empire interested in science and scientific method, in order, by joint action, to convince the people, by means of publications and meetings, of the necessity of applying the methods of science to all branches of human endeavour, and thus to further the progress and increase the welfare of the Empire.
- (2) To bring before the Government the scientific aspects of all matters affecting the national welfare.
- (3) To promote and extend the application of scientific principles to industrial and general purposes.
- (4) To promote scientific education by encouraging the support of universities and other institutions where the bounds of science are extended or where new applications of science are devised.

ORGANISATION.

All British subjects, both men and women, are eligible for membership of the guild; it is expected, however, that its members will be recruited principally from the following—the House of Lords, the House of Commons, Colonial Legislatures, county, district, borough, and parish councils; municipalities, educational committees, scientific and literary societies and organisations, commercial and industrial chambers and organisations, the learned professions, universities, colleges, educational bodies and graduates of all British universities, and representatives of labour. The Organising Committee is composed of the following:—Lord Avebury, Professor W. E. Ayrton, Sir George Sydenham Clarke, Captain E. W. Creak, Mr. Clive Cuthbertson, Dr. William Garnett, Dr. Sydney Lee, Sir Norman Lockyer, Lady Lockyer, Mr. N. MacColl, Professor Raphael Meldola, Professor J. Perry, Sir Gilbert Parker, M.P., Sir W. Ramsay, Dr. W. N. Shaw, Professor S. P. Thompson, Dr. A. Waller, and Sir Henry Trueman Wood. The Organising Committee has elected Sir Norman Lockyer president, Lord Avebury hon. treasurer, Lady Lockyer hon. assistant treasurer, and Mr. C. Cuthbertson hon. secretary. The committee is now engaged in communicating with those corporate bodies and individuals whose support and sympathy are desired. A general committee will be appointed, which will subsequently select from among its members an executive committee for the management of the affairs of the guild.

The following have already signified their general approval of the objects and proposed organisation of the guild:—Lord Alverstone, Sir John Wolfe-Barry, Dr. W. Blandford, Sir James Blyth, Mr. Brabrook, Sir George Birdwood, Sir John Brunner, Sir Lauder Brunton, Major-General Sir Owen Tudor Burne, Sir Edward Busk, Mr. R. H. Caird, Sir William Church, Sir John Cockburn, Professor W. E. Dalby, Dr. Ferrier, Sir Michael Foster, M.P., Sir Archibald Geikie, Sir Robert Giffen, Mr. Hammond-Chambers, K.C., Professor Herdman, Professor J. Larmor, Dr. Lockyer, Sir A. Noble, Lord Reay, Sir Wemyss Reid, Sir William Richmond, Sir Henry Roscoe, Mr. E. Robertson, M.P., Sir A. Rücker, Mr. Alex. Siemens, Lord Strathcona and Mount Royal, Sir L. Alma-Tadema, and Viscount Wolseley.

ADVERTISING by Photography.—A very progressive retailer has evolved a scheme in advertising for a country district which proved a great success. It was advertised that on a certain day a large photograph of the shop would be taken, and people from the surrounding country were invited to be present. It was further announced that everyone whose face appeared in the picture would be entitled to a free copy. The result was the biggest sort of an "opening." People even secured positions on the roof. In order to get a copy of the completed photograph, each person was obliged to call a second time, and on such an occasion would be apt to buy something. Besides the photographs would likely be preserved permanently, and would thus form a perennial advertisement.

THE AMERICAN AND EUROPEAN PHOTOGRAPHIC PRESS ON THE "B.J." JUBILEE.

OUR congratulations are extended to the *BRITISH JOURNAL OF PHOTOGRAPHY*. Its Jubilee issue is a volume in itself. We are glad that there is one staple publication, and particularly in the photographic field. It is to be hoped that the *BRITISH JOURNAL OF PHOTOGRAPHY* may continue its usefulness and celebrate its centennial.—"The Camera" (Philadelphia).

The *BRITISH JOURNAL OF PHOTOGRAPHY*, the oldest photographic journal in the world, in its issue of June 10, celebrates the beginning of the fifty-first volume. As would be expected, many of the old contributors indulge freely in interesting reminiscences, while the younger generation make practical contributions on modern subjects. Altogether, it is a large and interesting issue, and we can but wish it even greater success in the second half-century of its existence than it has had in the first.—"The Photo-Beacon" (Chicago).

The "Deutsche Photographen Zeitung" sends us its congratulations in the following short paragraph:—No. 2301 of the *BRITISH JOURNAL OF PHOTOGRAPHY* takes the form of a Jubilee Number, as fifty years have elapsed since the foundation of the paper. Consequently, this number is one of exceptional size, and is adorned with many pictures relating to photography. The portraits of the most important contributors to this paper are included, and the general character of the issue serves the one purpose in view. We congratulate the undertaking upon its Jubilee and hope it will have many more years of similar success.

Another German photographic paper—"Apollo"—also sends us its best wishes in the following terms:—No. 2301 of the *BRITISH JOURNAL OF PHOTOGRAPHY* (London, Henry Greenwood and Co.) appeared as a Jubilee Number, in commemoration of the fiftieth year of the paper's existence. The portly volume contains 75 pages devoted to numerous excellent treatises, many of which are by authors who have been active contributors to the *BRITISH JOURNAL OF PHOTOGRAPHY* from twenty to forty years. The Jubilee Number also contains an interesting history of the paper to which are added the portraits of its former and present editors. We wish this respected and worthy photographic paper the greatest success in the future.

The *BRITISH JOURNAL OF PHOTOGRAPHY* has just celebrated its fiftieth anniversary and its Jubilee Number, which came to hand this week, reviews its past history and its former editors, amongst whom we find such worthy names as Sir William Crookes, John Traill Taylor, W. B. Bolton, and Geo. Shadbolt. The *BRITISH JOURNAL*, like some of our monthly publications over here, started in life as a club journal, reporting from time to time the doings of the Liverpool Photographic Society, and it was only after various vicissitudes that it eventually came into its present proprietor's hands. The *BRITISH JOURNAL OF PHOTOGRAPHY* is not a lively paper, although very much a live paper. More professional than amateur, it does not pretend to cater to the beginner and it scoffs at the pretensions of the pictorialist. But it has done in the past and is doing in the present, a great work in the interests of photography, and I, for one, offer my heartiest congratulations to our esteemed contemporary, the staid, old *BRITISH JOURNAL OF PHOTOGRAPHY*. Long life to it!—"The Photographer" (New York).

The *BRITISH JOURNAL OF PHOTOGRAPHY* is the first among the photographic publications in the world to celebrate its fiftieth birthday anniversary. This event was celebrated by the publication of a sumptuous number of the journal under the name of the "Jubilee Number," in which is contained a vast amount of interesting and instructive matter, particularly of a retrospective nature. We would commend it to the attention of all who are interested in the past and present of photography. Published as it has been without interruption during all these years, it has steadily maintained a high position among the technical publications of Great Britain. Its policy has always been progressive, and its influence has been of decided weight in advancing the interest of our profession. The Jubilee Number is a fitting climax to its first fifty years, and should be interesting to the older members of the craft, for the reminiscences and experiences of the past, and to the younger members of the fraternity, as demonstrating some of the conditions under which their progenitors laboured in the early days of photography.—"Wilson's Photographic Magazine" (New York).

HALF-TONE ENGRAVING ON A RAILWAY FLIER

OUR contemporary, the "Daily Mirror," claims to have made a record which will be hard to beat.

Photographs illustrating the Tariff Reform demonstration at Welbeck Abbey were taken on Thursday afternoon, and reproduced in them appeared on the front page of the paper the next morning.

This, proceeds the "Mirror," may not sound particularly startling to the uninitiated, but it is a feat that has never before been accomplished in the history of journalism. Some time ago the "Mirror" was able to show its readers the reproduction of a photo of the winner of the Derby the day after the race was run. This was a record, but Epsom is so much nearer the metropolis than Welbeck that the photographs could be developed and the blocks from which the illustrations were printed could be made in London. Here the "Mirror" has special apparatus which enables photographs to be developed and process blocks made from them in record time. But Welbeck is 146 miles from London, and the record was much harder to make. It was accomplished by a happy combination of good management, and luck.

The negatives were taken by Mr. A. Seaman, of Chesterfield, whose well-equipped studio caused that town to be chosen as a work centre in preference to stations nearer Welbeck. A Beeston-Hul motor-car, supplied by the Cavendish Cycle Company of Chester, was waiting for the plates, and raced with them over the eight miles between Welbeck and Chesterfield. In less than an hour Mr. Seaman had developed his negatives and taken the excellent bromide prints from which the pictures were made. Then Messrs. Haider and Kettle, the process engravers, who with all the necessary apparatus had been despatched to Chesterfield by Messrs. Gee and Watson of St. Bride Street, at once set to work upon the photographs. Another hour pictures had been made from them upon zinc plates by means of the process camera. It was now getting on for five o'clock, and the London train was timed to leave Chesterfield twenty minutes past four. A special "Mirror" car was attached to the train, and in this the delicate work of engraving the plates was to be performed. It is 146 miles from Chesterfield to London, and the Midland Railway Company's train covers the distance in a little over three hours. During a great part of this journey the train is travelling at the rate of 60 to 65 miles an hour.

Never before have process blocks been made under such circumstances. The swaying of the train as it rattled over the metals made it almost impossible to keep the graver upon the surface of the metal. Each jar splashed the acids that are employed in the process of engraving the tanks, and necessitated their frequent refilling. But the work was accomplished, and, under the circumstances, to the great credit of all concerned. Half an hour before St. Pancras was reached the engravers were able to inspect their finished work. The "Mirror" motor-car waiting at the station snatched the plates and took them to the office in good time for press. The following is a time-table of the work performed:—

1. 0.—Photos taken.
- 1.45.—Motor-car reaches Chesterfield (18 miles).
- 2.45.—Pictures finished by Mr. Seaman.
- 3.45.—Zinc plate made.
- 4.21.—Train left Chesterfield.
- 7.50.—Train arrived St. Pancras.
8. 0.—Plates reach "Mirror" office.

The successful accomplishment of this feat is due in the first place to the enterprise of Messrs. Gee and Watson, of 20, St. Bride Street, and the skill of Messrs. Haider and Kettle, their employees. A great deal of credit must be given to Mr. Seaman, of Chesterfield, who performed his share of the work with skill and despatch.

In drying photographic plates, the electrically driven fan motor offers a means of greatly accelerating the process. This may often be done in twenty minutes or half an hour, by setting the plates in front of an ordinary 110-volt fan motor; but great care must be taken to allow dust to accumulate upon the film of the plates as a result of the blowing process.

THE GREAT SIZE OF THE ST. LOUIS EXPOSITION.

American people are credited with a love for big things; and the mere element of bigness were its strongest attraction, writes "Scientific American," the great Exposition at St. Louis ought to be the most popular and successful of the many exhibitions of the kind to which the country has been treated during the past decade. Yet anyone who is present on the grounds, and takes a careful note of the vast throngs which are to be found trying to get the round of the two square miles that are devoted to the Exposition, will be forced to the conviction that if the mere size of the Fair is an attraction, it is an attraction that is more of a sentimental than of a practical character; for it must be conceded that for the average visitor, with only limited time at his disposal, the Exposition of 1904 is altogether too big.

Judged from the merely spectacular side, the vast proportions which this enterprise has been planned and carried out have served their purpose well; for a view of this wonderful congregation of buildings, taken, let us say, from the steps of the great Festival Hall, is certainly magnificent, beautiful, and artistically impressive as anything that could well be imagined. But when, by giving himself up to the emotions that are aroused by this splendid panorama, the like of which will probably never be seen again, the visitor sets himself resolutely to the work of inspecting the buildings and their exhibits, the conviction is soon borne in upon him that to gain anything more than a cursory glimpse would require a work calling for several weeks, if not months, of study. The problem is particularly serious, if he is desirous of following up only the main lines of exhibits, which may be, and probably are, scattered throughout several different buildings on the grounds. The exhibition palaces themselves are so immense, the distances between them so great, that it is impossible to follow out a line of investigation of this kind consecutively, day after day, without becoming practically exhausted.

Now we say this, not in any spirit of unkindly criticism, but merely to draw attention to the fact that in the endeavour to make the International Fair of this kind represent, by its vast proportions, the extent of the resources, the range of the industries, of the country which it represents, the limits of practical usefulness have been far exceeded. It must already have forced itself upon the sponsors of this exposition that future exhibitions of the kind must be restricted in their dimensions.

The difficulties of adequately seeing the Fair and inspecting in detail the various exhibits, might have been largely reduced if the Intramural Railway System had covered at least four times as much ground as it already does. At present, as actually built, in making the outside circuit of the grounds it covers a total distance of about eight miles; and when we remember that the Exposition grounds, which are in the form of a parallelogram, measure one mile in width by one and three-quarters in length, it can be understood that the distances across the main group of buildings, encircled by this road, are necessarily very great. Had intersecting lines of track been run in gridiron fashion through the main plazas and passageways, the problem of transportation would have been greatly simplified. Nor would the presence of these tracks have marred the landscape and architectural effects. So vast are the various plazas and courts, that the presence of the trains would scarcely have been noticed.

To give some idea of the great scale upon which the place is laid out, let us consider one single building, the Palace of Agriculture. The plan of this structure is a parallelogram, which extends in width for five hundred feet and in length for sixteen hundred feet. It contains eight or nine corridors, each sixteen hundred feet in length, crowded each of them on both sides with exhibits, and it is intersected throughout its full length with numerous transverse corridors. This means that anyone wishing to cover the whole field of exhibits within this single building, would have to walk at least three or four miles. The other industrial palaces, though not so large as this, are every one of them of great proportions. Thus the United States Government Building is 250 feet wide by 800 feet long; the Palace of Mines and Metallurgy is over twice that width and of about the same length. Then we have the Palace of Manu-

factures, 1,200 feet in length by 525 feet in width; the Palace of Varied Industries of the same dimensions; and the Palace of Transportation of the same width, but 1,300 feet in length. And so it runs, each of these buildings containing a covered acreage that would represent a large proportion of the total area that was under roof at the Centennial Exposition at Philadelphia.

To those people for whom the theories of Bellamy have an attraction, the problem of attempting to house 5,000 people in a single hotel within the grounds will present a decidedly interesting study. Of course, nothing of the kind, or even approaching it, has ever before been attempted; and considering the ambitious scale on which the hotel is being run, probably the guests are securing about all they can reasonably ask for. But here again the distances to be traversed become a serious problem, as may be judged from the fact that the writer, on starting out for the day, found that a rainstorm was threatening, and in returning to his room for an umbrella had to cover nearly half a mile of walking before he was back at the main entrance.

FORTHCOMING EXHIBITIONS.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 1-30.—Berlin International Photographic Exposition. M. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 15-29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute, Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

October 19-22.—Rotherham Photographic Society. Hon. Sec., H. C. Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Park, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hill-head, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Patent News.

The following applications for Patents were made between July 25 and July 30, 1904:—

Tripod Head.—No. 16,359. "Improvements in or connected with tripod heads for photographic purposes." John Ambrose Sprason.

Cameras.—No. 16,507. "Improvements in and relating to photographic cameras, and to a check exposing device thereon." Complete specification. Frederic Edgar Cheesman.

Film Case.—No. 16,526. "Improved case or cassette for flat films, plates, and the like." (Date applied for under Patents Act, 1901, 28th July, 1903, being date of application in Germany.) Complete specification. Robert Krayn.

Cameras.—No. 16,572. "Improvements in photographic cameras." Robert Scott.

Colour Filters.—No. 16,659. "Improvements in and relating to mounting and operation of photographic colour filters." Complete specification. Hans Schmidt.

THE Unofocal Lens. At the request of several correspondents we republish the Astigmatism Chart of the Unofocal Lens, as given with the report of Mr. Beck's lecture at the Royal Photographic Society in our issue for July 15:—

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
15.....	Bowes Pk. and District Ph. Soc.	Competition. Outing Prints.
16.....	Nelson Photographic Society...	Members' Print Evening.
17.....	North Middlesex Photo. Soc. ...	Indoor Portraiture. Mr. G. Williams.

CATFORD AND FOREST HILL PHOTOGRAPHIC SOCIETY. MEMBERS of this society met at Keston on Saturday last for purpose of photographing the picturesque spots surrounding the lake. Mr. J. Wheeler Bennett granted the party permission to enter beautiful grounds, and it was here that the amateurs were busily employed during most of the time, some very successful pictures being produced. Unfortunately, the early part of the afternoon was not propitious, owing to dark clouds and showers, later the sun shone brilliantly, and the clear atmosphere, which usually follows a shower, afforded excellent conditions for enthusiastic photographers. All expressed themselves delighted with the day's doings, and many hoped that the visit might be repeated at an early date. Mr. A. W. Nunn, F.C.S., was the conductor on this occasion.

THE PHOTOGRAPHIC SOCIETY OF INDIA.

THE Photographic Society of India, on July 8th, gave an "Home" at No. 40, Chowringhi, to bid farewell to Mr. N. Giannacopulo, the president of the society, who is shortly retiring from India. There was a large attendance of ladies and gentlemen. An excellent exhibition of lantern slides was first given, comprising views of "Sunset on the Hughlie," by Fr. Oldbury Burne; "In the Flowers," coloured in oil by Mrs. Wilson; "Sunssets," by Mr. Art. Norman; a series of slides by Mr. A. J. Oliver, including some specially fine views of the Kali Caves; some interesting views of Dalny and Port Arthur, by Mr. H. M. Bretten; and last, though not least, some beautifully coloured views from Japan. Mr. Art. Norman, one of the vice-presidents of the society, in an appropriate speech alluded to Mr. Giannacopulo's connection with the society since 1886. He thanked Mr. Giannacopulo for the amount of trouble and trouble the latter had expended on their behalf, and asked him to accept a silver salver and a silver tea service, which had been subscribed for among them, hoping that they would be of use to him, and also that they might keep the recollection of the meeting out here fresh in his memory. Mr. Giannacopulo, in acknowledging the presentation of the handsome souvenir, said that he had taken a great interest in the society ever since it was started seventeen or eighteen years ago. There was a saying that India was a land of regrets, but he doubted if any of them really realised its meaning until they were about to quit its shores. They did not regret its heat and its muggy rains, nor yet the amusements of the cold weather, but the real and heartfelt regret was the parting with good friends. This souvenir would be treasured and have the place of honour in his new home. He would take this opportunity of saying good-bye.

SOUTHAMPTON CAMERA CLUB.

AUGUST 8TH.—At a meeting of the members of this club, under the presidency of Mr. G. T. Vivian, a print competition took place the subject being "Southampton Common." Each set of prints consisted of three, and a prize of £1 was offered by Mr. Council S. Tebbutt for the best set. Over twenty sets were proffered for competition, and the contributions were of such an excellent order that the judges (Messrs. R. McFadden and G. T. Vivian) experienced great difficulty in allotting the places of honour, but ultimately bracketed Messrs. C. C. Cook and Geo. R. Johnson for the premier position. A similar difficulty arose for second honours, which had to be shared by Messrs. G. Fridge and H. W. Miles. The competition being of so keen a nature, 10s. were voted from the club fund as a second prize. The prints generally were of a very satisfactory character, and place beyond doubt the unlimited resources of Southampton Common for such purposes. It was decided to place the matter before the committee with a view to considering the most suitable means of preserving such an excellent and representative collection of views of Southampton's miniature forest.

DR. C. F. GRINDROD'S PICTORIAL PHOTOGRAPHS.

THE twelve reproductions of Dr. C. F. Grindrod's photographs which constitute the tasteful and handsome album that has been sent by the Photochrome Company, of 35 and 36, Hosier Lane, Snow Hill, E.C., might at the first glance deceive even an expert in process matters. They look for all the world like prints in brown carbon pigment. But they are not. They are half-tone impressions on paper having an intaglio surface, which, with the very skilfully-chosen ink employed, operates to produce a distinctly pleasing result. In phototypic printing the end justifies the means, and the latter, in the present case, are, without doubt, successful.

Dr. Grindrod finds a prelatory appreciator in the person of his confrère, Mr. H. Snowden Ward, who descants upon the genial silvern worker's "New Outlook upon Life," and his ability to show us "Something of the Sturdy Dignity of Swine." We suspect

take occasion to commend the collection, as a whole, to the lover of nature photographs which do not offer you riddles for solution before you know the meaning of them. Each example is worth a frame, and as the album costs only 3s. 6d., an excellent collection of artistic photographic work may be had cheaply. The appended illustration is given by courtesy of the Photochrome Company. In conclusion, we would thank Dr. Grindrod for the rich bit of humour, "The March Home," a flock of geese waddling past a stone inscribed, "116 miles from London." The deadly dullness and appallingly unimaginative monotony of pictorial photography of the bepuffed-up exhibition kind is only too infrequently relieved by such delicious achievements as these.

TECHNICAL OPTICS.—Day courses in Technical Optics, to meet the requirements of those who desire a more thorough training than can

A FOREST GIANT'S FUNERAL.

[Dr. C. Grindrod.

that Mr. Ward has been sitting at the feet of Mr. Hartmann, the glorious inventor of plastic psychological syntheses and other fearful wild photographs. You can carry this sort of thing to such lengths that even the late Mr. Robert Browning will appear, by comparison, a marvel of verbal and descriptive lucidity. Now, it is not as an interpreter of porcine dignity that Dr. Grindrod appeals, or appears, to us, but rather as the sympathetic student of field life which he illustrates by the aid of the camera. He is quite one of the Emerson school—humorous, and observant, and with a keen eye for the proper grouping of figures. Such specimens as "The Ferry Boat," "In Noonday Heat," and "The Harvesters," quite recall Emerson's earlier work. Here and there we have a suggestion of Gale, as, for example, in "Getting Tired," a reaping scene at "Close of Day."

But detailed criticism of these charming specimens of photographic work is not on the present occasion called for. We would rather

be obtained in evening classes, will be established at the Northampton Institute, for the session 1904-5. The chief object will be so to train the students, both theoretically and practically, that they will be in a position on leaving the institution to deal with the numerous scientific and practical problems which all who aspire to take the higher positions in the optical trades must be prepared to solve.

SUNDERLAND Camera Club.—The Sunderland Camera Club is to hold an Open Photographic Exhibition this year in St. Peter's Schoolrooms, Green Street, Sunderland, on November 15 to 19. The Rev. F. C. Lambert, F.R.P.S., and Mr. F. M. Sutcliffe, of Whitby, will act as judges. There are six classes, one of which is confined to photographers resident in Northumberland and Durham. In place of medals, handsome plaques specially designed by R. J. S. Bertram, of Newcastle-on-Tyne, will be awarded in each class. The prospectus will be issued shortly by Mr. Selby Ord, 52, Frederick Street, Sunderland.

Commercial & Legal Intelligence

WE learn from the London Scientific and Novelty Supply Co., of 1, Clerkenwell Close, London, E.C., that they have taken over the photographic and stereoscopic plant, etc., of Mr. A. Pumpherly, of Birmingham.

AN improvement in photographic "blue" printing is mentioned in patent No. 6,930,103 whereby the electric arc is made to descend at a predetermined speed within the glass cylinder around which the tracing to be copied is mounted, thereby enabling correctly timed blue prints to be obtained automatically, such being effected by means of a piston within a cylinder and to which is mounted a piston rod on the end of which is arranged a rack to operate glazing for rotating the drum around which the cord that is attached to the lamp is wound. The movement of the piston within the cylinder is obtained by the displacement of oil from the upper or lower to the lower or upper surface of the piston through the medium of a pipe outside the cylinder. The pipe is provided with a valve for regulating the flow of the oil.

AN Extraordinary Reception.—At the West Riding Assizes, on Thursday last, Annie Millimore (30), Annie Clare (29), and Albert Fieldhouse (25), were indicted for robbery with violence, with another person, on Morris Kitchen, and stealing from him a cigarette case and 2s., at Bradford on May 6. Mr. Harold Newell prosecuted and Mr. Percy Middleton defended Clare. The prosecutor is a Russian and canvassed for orders for enlargements of photographs for the United States Art Company. On May 6 he went in search of business into Back Ebenezer Street, Bradford. Kitchen's story was that he knocked at a house door and was invited to go in. He opened the door and entered. Inside he found three women, including the two prisoners. Clare at once acted in an indecent manner and asked him for some money. A moment later Fieldhouse came downstairs, seized Kitchen by the neck, and held him while the women rifled his pockets. Next day the prosecutor identified the two female prisoners and the man, but was unable to identify the third woman. The female prisoners both blamed the other for what had occurred, and denied that they personally participated in the robbery. Fieldhouse declared that he was not in the house at the time. In summing up, the Judge remarked upon the "enthusiastic manner" in which the prosecutor had carried on his canvassing, and the "extraordinary reception" he had met with at the house in question. The jury found all the prisoners guilty, and a Bradford detective gave them very indifferent characters. Fieldhouse was sentenced to nine months' hard labour and the two women to six months' hard labour.

CHARGE of Fraud Dismissed.—The Redditch magistrates were occupied a considerable time on August 3rd in hearing a case in which Robert Hayward, 15, Gooch Road, Sparkhill, and Frederick Miller Bickmore, 142, Grove Road, Sparkhill, were charged with obtaining with intent to defraud 3s. from Mr. Clive Taylor, George Street, Redditch. It was stated that prisoners called on prosecutor and represented they were engaged by the Midland Counties Photographic Company, County Chambers, Corporation Street, Birmingham, in conjunction with Messrs. A. and G. Taylor, photographers, Redditch, and on the strength of their statements Mr. Taylor gave them 3s. as a deposit towards the cost of a photograph of a family group which was to be executed. Joseph Ginns, manager of the Midland Counties Photographic Company in Redditch, said prisoners had no authority to represent the company in Redditch, and they had not accounted to him for the sum they had from Mr. Taylor. Police-Sergeant Branton deposed receiving prisoners from the Sparkhill police. Prisoners had books with duplicate forms in their possession, and also specimens of photographs, all relating to the Coventry branch of the Midland Counties Photographic Company, Birmingham. Walter Tandy, manager of the Midland Counties Photographic Company, Birmingham, stated that on July 21 he started prisoners off for Coventry. Their duties were to canvass in Coventry. They were to report themselves to the manager there, and had no right to canvass at Redditch. It was the rule for them to report to the branch managers the results of their work. In this case prisoners had not reported to the manager. Prisoners' defence was that the rule referred to by the

manager had never been rigidly observed and that the books of town had frequently been used for other towns.—The Bench said that there was not sufficient evidence to justify sending prisoners to trial and discharged them. Another and similar charge against prisoners was also dismissed, and Superintendent Hayes would proceed with a third.

IMPROPER Picture Postcards.—At Stonehouse last week, before Messrs. W. H. Jennings and J. S. Hawker, William Bartlett Lutwenty-two, Manor Street, was charged with offering for sale improper prints.—Mr. J. P. Dobell appeared for defendant, who pleaded guilty.—P. S. Richards stated that on July 25, acting on the instructions of Supt. Hacon, he went to defendant's shop, and said he wanted to buy some picture postcards similar to those in the window. They were offered at 2d. each, and he purchased the eight cards produced for 1s. On July 30 he bought the three postcards produced, and when he was on sale at the time of his previous visit to the shop.—Mr. Dobell handed witness a copy of a London periodical, dated August 3, and asked witness whether several small pictures called "Art Plates" contained therein would not, if they were coloured, be something of the same nature as the postcards produced.—Witness replied that he should not think so.—Dr. Dobell: Do you consider the exposure of limbs is the improper part?—Witness: I leave that to the magistrates. Dr. Dobell asked under what Act the proceedings were taken, and was told the Towns Police Clauses Act.—Mr. Dobell read the section and pointed out that it commenced with the words "Every person who in any street, to the obstruction, annoyance, or danger of residents or passengers commits any of the following offences." He submitted that unless the sale took place in the street there was no offence. The postcards in question were sold in a shop, and that had been held not to be the same as street under the Act.—The Bench decided against Mr. Dobell, the chairman remarking that the prints being exposed in a shop window and priced was a public offer of sale. Dr. Dobell asked for a note to be taken of his objection, and, continuing his defence, said that defendant had been a resident in Manor Street for nearly twenty years, and if he thought that the prints were such as contravened the statute he would not have been the means of circulating them. He did not say that they were not vulgar, but did say that they were not improper. The magistrates should have regard to the locality in which they were offered for sale. When might be considered vulgar in Durnford Street or Chapel Street might have a very different significance in Manor Street. Was there anything more improper in the postcards produced than in the "Art Plates" in the periodical he had handed to the magistrates, which might be found on almost every drawing-room table in the kingdom? Except that they were not coloured, those pictures were quite suggestive to people affected by such productions as any of the postcards in that case.—The Chairman said it was the opinion of the Bench that the postcards produced were improper and disgusting, and it was a matter of surprise that anyone claiming to be a respectable tradesman should deal in such pictures. They had decided to inflict a penalty of 40s., inclusive of costs.—Mr. Dobell gave notice of appeal on the legal question he had raised.

News and Notes.

No. 62 of the "Photo Miniature" is to hand. This latest addition to the series deals with the topical subject of "Vacation Photography."

MR. RICHARD KEARTON, the distinguished photographer and describer of wild life, has been suffering from appendicitis. An operation has just been successfully performed, and he is progressing favourably.

WE are indebted to an African correspondent, Mr. Percy M. Clark, for an album of views of the Victoria Falls and neighbourhood. Published by Mr. Ellis Allen, stationer, Main Street, Bulawayo, the views are printed from half-tone blocks, and the pictures give one a very good idea of the grandeur and the magnificence of the Zambesi river.

THE Coatbridge Photographic Association holds its second annual exhibition in the Photographic Institute, Coatbridge, from Saturday

October 15, to Saturday, October 29, inclusive. The judges will be Messrs. W. M. Warneke, Arch. Cochrane, and T. W. Robertson, and the secretary is Mr. G. W. Campbell, Ailsa Cottage, Coatbridge, N.B. There are six open classes, and silver and bronze medals are offered for each. The entries close October 3.

The proposed Dublin Permanent Gallery of Modern Pictures is so far a thing accomplished that, under a guarantee of friends, two works of art, worthy of the name, have been already secured. These are a bronze by Rodin, and the "En Voyage"—a portrait of the artist's mother—exhibited by Signor Mancini in the Royal Academy exhibition just closed. International rivalry is as likely as a Committee of Inquiry to supply the Chantry trustees with a prod, and Dublin is to be congratulated on having now bought what should have been secured for the Tate Gallery last May.

The picture postcard is a never-failing source of delight to many persons, though it adds another terror to travel if the traveller has many collectors on his list of friends. But great interest will be created even among those who have not yet succumbed to the mania by the announcement in a Japanese paper that the authorities of the Empire intend to issue pictorial postcards "as souvenirs of the war." The intimation is added that "the cards will be first distributed among the officers and men at the front, and the remainder, if any, will be sold to the public." The reservation "if any" seems to betoken a short supply and high prices. But the British public will prove equal to the severest financial emergency in such a case.

DURING these summer and autumn evenings the planet Saturn may be seen rather low down near the southern horizon, about ten or eleven o'clock. The ringed planet is specially interesting to astronomers just now, for he is suspected of having had an addition to his family. Saturn has for certain eight satellites or moons, which have been discovered at intervals between the years 1655 and 1848. In the year 1899 a ninth satellite was reported to be shown by a photograph taken at Harvard College Observatory; but the evidence was not deemed to be conclusive. Lately, however, information given with much confidence comes from America that the satellite has been again seen on photographs taken this year at the same observatory. The ninth moon is excessively minute, so that none but possessors of the largest instruments can hope to see it.

The "Graphic" Photographic Competition.—The previous "Graphic" Photographic Competitions met with such great success, and attracted so much interest amongst amateur photographers, who sent in many thousand contributions, that the proprietors of the "Graphic" have decided to hold another competition, and to offer prizes of £20, £15, £10, and £5. The prize photographs will be published in the "Graphic," together with any others which the judges think worthy of special mention. The fee of one guinea will be paid for each photograph reproduced, with the exception of the prize photographs. At the last competition a large number of photographs were selected by the judges for publication and special mention, in addition to the prize photographs. Full particulars can be obtained on application to the manager of the "Graphic" Amateur Photographic Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

ROYALTY and Engraving.—There was an interesting item in the single speech which constituted the toast list at the outing if Mr. Carl Hentschel's employees on Saturday. The three or four hundred employees of this engraving firm met under the shadow of Windsor Castle at the White Hart Hotel, Windsor; and this prompted Mr. Carl Hentschel to mention that King Edward was so pleased with a large portrait of himself executed by the firm by the familiar "three colour" process, that he signed a proof and sent it to the Kaiser as his Christmas card. Mr. Hentschel also told the company that when the Prince and Princess of Wales recently visited the new "Graphic" offices they were exceedingly interested examiners of the methods of process engraving as there in evidence. The details of working, the negatives, and subsequent preparations of plates were briefly and lucidly explained to the Royal visitors. It may be added that this interest is hereditary. Queen Victoria and the Prince Consort having been enthusiastic amateur etchers. Many a plate embodying their workmanship

was etched in Windsor Castle. Mr. Hentschel said the public had no idea of the rush and strain under which plates illustrating events of the day were now habitually produced, two hours having to suffice for work for which twenty years ago twenty hours would have been demanded by the platemakers. A hint to manufacturers in various industries was offered, when Mr. Hentschel remarked that, during the "heat wave," the hundred workers engaged in the colour-plate department of the firm at Norwood had begun work at five in the morning and left off at noon.

"THE Camera Can't Lie."—The great advance which has been made in the newspaper world in the past decade through the employment of the camera as an adjunct to the gathering of news is dwelt on by the "Times-Star" of Cincinnati. The vogue of the camera is chiefly due to its truth-telling proclivities," says our contemporary. "A forcible illustration of this is given in the London 'Leader.' Reuter's News Agency sent out from Bombay a despatch to the effect that on the departure of Lord Curzon for England that Viceroy's route from the station was thronged with large crowds which displayed much enthusiasm. The 'Leader' reproduces a photograph from the 'Empress' of Calcutta, which ought to bring a few explanations from the Reuter's correspondent. The picture shows Lord Curzon's carriage passing the Bombay Club. First came a squad of horsemen in Indian costume, then the Viceroy's carriage, then more turbaned riders, and in the distance a few more. On each side of the procession is a long line of soldiers presenting arms. But what are the soldiers there for? 'To keep back the thronged populace,' Reuter's man would probably answer. But where is the thronging populace, where these large crowds, which displayed marked enthusiasm? Alas, where? A group of forty or fifty people are standing at the junction of two streets, idly watching the parade. There are no waving caps. On the other side of the car-tracks are a few bicyclists, cabs, and foot passengers. Everybody appears to be going about his business, paying no more attention to the representative of the Emperor than if he were a wealthy merchant driving down to his office. The 'Leader' says: 'There is a sense of desolation in the picture that can almost be felt,' and that is putting it mildly. If it is an illustration of 'marked enthusiasm,' the 'Empress' would oblige us by furnishing a picture showing Indian apathy."

SOME points in landscape photography. One of the principal difficulties in landscape work where a satisfactory pictorial effect is desired lies in the elimination of the unnecessary, writes a photographic correspondent to the "Newcastle Chronicle." With regard to the proper arrangement of the parts of the picture, it is generally possible to so choose the point of view that the composition shall be more or less what is right, because a movement of a few yards does not materially alter the appearance of distant objects, while the foreground objects may occupy quite different positions in the picture. It is also often quite easy to move some of the foreground stuff, rolling a log of wood to a different place, pulling up a few tufts of dog daisies, carrying a couple of boats' anchors to such a position that they properly break up the foreground and arranging the ropes attached to them so that they do not form curving lines leading into the picture, and so on. But to exclude what is not wanted cannot always be so readily accomplished. It may be done sometimes by dodging one object behind another. At other times it is possible to get, say a chimney or telegraph post near to the edge of the plate, even if it cannot be got out of the picture entirely. Then a little retouching medium, followed by careful pencilling, will usually be sufficient to obliterate a small object. Telegraph wires are frequently a source of much annoyance. If they come quite close to the lens, they will sometimes not show at all, especially if care be taken to give a full exposure. But when twenty or thirty yards from the camera they show very aggressively, particularly if one of the anastigmat lenses is being employed. The best thing in such a case is to get them as much out of the focus as possible, and then to pencil carefully over the marks. It is always easier to work out a blurry, ill-defined mark, than one with sharp clear edges. Light objects, such as a white piece of paper, a child in light dress who happens to have moved, or anything lighter than its background, must, of course, be obliterated by scraping, the scraping being followed by pencilling until the even tone or tones of the background are filled in.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

THE FUTURE OF PROFESSIONAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—Having read with interest the articles appearing from time to time in your columns re the future of photography, I should like to add my humble opinion and testimony to what has already been written on the subject. The outlook is certainly anything but cheering, either for employer or employee, and I take it that this state of things is due to several causes. Competition has effectually stopped the amassing of fortunes by employers, and in another direction has been equally disastrous to assistants. The ease with which a superficial knowledge of photography can be obtained, owing to the advent of dry plates, up-to-date apparatus, the almost mechanical forms of printing papers, etc., renders it possible for anyone to turn out passable work with very little practice and theoretical knowledge; consequently our ranks are being swelled every year by amateurs and improvers, who are filling berths which a few years ago would have required a really good pro. Again there are hundreds of people being trained every year at the various Polytechnics and similar institutions, at a fee of a few shillings a term, who, when they attain anything approaching proficiency, help still further to crowd the labour market.

The competition already referred to has caused hundreds of business men to cut down their prices to an absolutely ridiculous figure, thereby rendering it impossible for them to pay a fair living wage to their assistants, and here especially the mediocre worker comes in, and, in lieu of anything better, is glad to accept the magnificent salary of £1 or £1 5s. so impudently offered in the Situations Vacant Column, to say nothing of the (not afraid of work), whose work is quite good enough for the class of business. Photography, being a light, non-laborious means of livelihood, ladies are crowding into it, who can afford to work for salaries which it would be impossible for a man to entertain, especially if, as in many cases, he is married. I do not wish for one moment to hurt the feelings of any ladies reading this, but the fact remains nevertheless, and my advice to those about to enter the profession is Punch's advice to young men about to marry, "Don't," for the prospect for ladies in photography is by no means rosy.

The foregoing, however, refers principally to the third and fourth rate photographer, and, so far as it goes, should not affect the really competent ladies and gentlemen who find employment in our first-class firms, but (and in my opinion this is the most lamentable part of the business) the cutting down of salaries is by no means confined to the inferior worker, but has extended even to our best houses, where, to my knowledge, the ratio has been reduced quite 50 per cent., and I am not stating this merely from hearsay, as only a very short time ago I myself was offered the princely sum of £3 per week as operator and manager by two of our leading West-End firms, and £2 and commission by another. There is no excuse here of unskilled labour or of having to cut prices to suit the clientèle, or of an almost impossible task to pay the rent, etc. With a poor struggling master it is in a measure understandable and very excusable for him to pay a low wage, but, notwithstanding the general depression in business, there is no necessity for the best houses, whose business is entirely with aristocracy, to cut their assistants down in this shameful manner, and especially when we consider the qualifications necessary to obtain an engagement with these firms, which are as follows:—Absolute proficiency, both technical and artistic, good education, deportment and conversation, almost unlimited patience to deal with children, and oft-times rude and crotchety adults, especially found among the upper classes, a faultless appearance, and, in many cases, smart business capabilities. I also know that ladies applying for positions as receptionists to some of these firms have been offered 15s. per week, which is far less than that given by a certain firm of three for 2s. 6d. with coupon, who pay a 10 per cent. commission, as well as a little salary.

The question is, how much farther can this state of affairs go?

Surely it must have by now reached the limit; if not, we may expect very soon to see advertisements something as follows:—"A gentleman of ability required by a firm of Court photographers as operator and manager; only those with experience in highest class studios invited to apply. Permanency to really clever man. Salary £3 rising to £1 10s."

In conclusion, may I say that it is my firm opinion that employers very often considerably over-reach themselves and lose far more than they gain by this policy of grinding Shylockism, as, for my part, I would do my very utmost to improve the business for an employer who considered my interests a little as well as his own, but I should certainly not put myself out a little bit for a man who regarded me merely as a machine, for which he begrudged me a little oil; making all allowance for the degeneracy of human nature, I venture to affirm that in this respect I by no means stand alone.—Yours sincerely,

August 6th, 1904.

[Mediocrity unhappily abounds in professional photography; really good workers are scarce. Is it not the case that the low rates of wages at present current in the photographic labour market is directly caused by the poor quality of the ability at the command of employers?—Eds. B.J.P.]

DEVELOPERS WITH ACETONE.

To the Editors.

Gentlemen,—With regard to Mr. Smith's letter re my remarks on acetone developers, I took three minutes for the pyro-acetone developer and eight minutes for the ferrous oxalate (the exposures being the same), because these are about the times usually given in practice for developing an actual negative with the developers respectively, and I think such a comparison serves better than a scientifically comparative one for the class of readers my article was intended to interest. Mr. Smith is quite right in his remarks, but we are merely looking at things from different standpoints.

I beg to thank Mr. Smith for pointing out my misquotation from Eder. I only cursorily glanced through the article referred to, and was under the impression that I have read in other Continental works that Cyspek had obtained results with acetone as early as anyone. I believe that Vogel and Valenta were as early in the field, almost anybody, but definite historical notes are difficult to obtain on this subject.—I am, yours faithfully,

T. THORNE BAKER

16, Rutland Park Mansions, Willesden Green, N.W.

August 5, 1904.

THE STEADMAN SYSTEM OF EXPOSURE.

To the Editors.

Gentlemen,—I am asking myself whether the weather or aught else has contributed to my being exceedingly dense after reading the article upon this subject on page 686 in your last issue. I am sorry to say that there is a very negative result to me after wading through it, and should like very much to know what some other fellows think of it. It seems to me, on the face of it, to be American in production, it has much wind about it, and that delightful factor (of which Americans are so proud in their way of stating things) of being twice as long as it need be to tell the story. Of course, because it may be American, it need not damn it, any more than because I can get no light—or very little—out of it. If it is an English production perhaps we ought to be very proud of it, as a duck that is a swan should be, but I shall be glad to know what the other fellows think.

Anyway, what, I wonder, do the other fellows imagine is "a plainly observable tint"? Does this depend upon the colour sense of the observer, because everybody has not the same notion of a tint, except, perhaps, in connection with soda water—say. If it does, then one person's observation would give a longer exposure than another's. What is the rate of speed, or exposure time, of a plate which I use? It is not given on the plate boxes, and how does such an expression help general practice?

Will some of the fellows who have gripped this thing in their beak put it into ordinary, terse English—say in two hundred words—tell all they know?

London time we know, New York time we know, St. Louis time we know, Chicago, and 'Frisco time we know; but what in its simplicity

to time? Is it kodak time? But, there, it is spelled with "s" and not "8."—I am, yours, etc.,
JNO. NINNYHAMMER.
August 5, 1904.

A PART GREATER THAN ITS WHOLE.

To the Editors.

Gentlemen,—If man had been constructed in as definite and as varying a way as a geometrical figure it would be impossible in his life to go beyond the Euclidian axiom that—"the whole is greater than its part." He has, however, a good deal more about him than a geometrical figure or shape, which limits the field of application of the axiom. Upon his artistic side—as befitting the complete contrast between the freedom of art and the rigidity of geometry—the axiom may even be completely reversed and the contrary statement be regarded as perfectly true, that the part is greater than the whole. Indeed, every artist recognises the truth of the fact, and acts upon it. In depicting a face, a form, a landscape, or an incident he never gives more than a part. He knows very well from his own experience that the imagination must be given room for action, and that if he seeks to lead that imagination unduly by lengthening its leading strings in giving fuller detail it will resent its effort. He also knows that as imaginations vary with position in life, training, intellectual capacity, and constitutional temperament the more likelihood there is of providing stumbling-blocks and diminishing the circle of appreciation of his picture by introducing what his particular imagination, however high an opinion he may have of it, may regard as extremely telling detail. This bottom principle and practice of the artist is well worth the consideration and adoption of the photographer in the effort at improving his work in the broader fields lying outside the bounds of the purely technical. The photographer's disadvantage, compared with the artist, of not being compelled to submit every item in his proposed picture to the criterion of his judgment—or, rather, of submitting the whole to a process of mental and psychological digestion for the assimilation and consequent expression of the best. Still, whilst not compelled to do so by the working methods of his craft, he might do so as far as practicable with a corresponding gain in results.

The wide range of working photographic conditions at this time of the year makes it a tempting season for trial of the principle. The dawn comes early and the sunset is late; shadows can be caught at any and all lengths; every dark and cool recess has its particular penetrative maximum of light; and if it is desired to catch movement exposures are at their shortest. Finally, it is the holiday season, with its spare time for thought and practice. An examination of the artist's picture will prove that although he may only have shown part it is the right part and right in expressing what is characteristic. "A Cornish Village"—merely a scrap, cottagy street, a boat or two; a fisherman leaning against a post, and the free sea. Surely there is a point of view from which the same thing could be taken with a camera! The great thing is to approach the photographing of the village from the same mental as well as physical point of view as the artist. It is rather a difficult matter for the photographer to select the right part upon his screen, as so much that cannot be wanted is shown at the same time, and tends to disturb the judgment by its presence—usually prominent presence, to boot. The orthodox effort to produce a perfect negative also tells against success. The final positive print is the real thing, and if in that the characteristic part can be got by blocking out, vignetting, or by other expedient, any objectionable detail, there is no reason why the latter may not be accepted and included in the negative if without its inclusion the desired part is impracticable. To assist the judgment in selecting and composing, a piece of paper placed over what is undesirable on the screen will serve. "Somewhere-on-Thames" again—water, a boat, a lane leading up from the river, a riverside inn or cottage, with roofs amongst the trees in the distance. The elements are simple enough, and a score of such pictures will immediately suggest themselves to anyone who has any knowledge of the river. Or, as to the lower river below London Bridge, the many excellent representations upon pictorial postcards will give all hints to the photographer, with artistic instincts of what he needs if he subscribes to the view that "the part is greater than the whole."

Where length of exposure will permit of its use the telephoto lens gives a great aid in this particular form of photographic expression. It sifts away such a large amount of extraneous detail. It is a pity

that the peculiar power of this lens to represent objects at comparatively near should have been overshadowed by its capacity to work also at telescopic distances. The difficulty in focussing is a serious one. If this could be overcome by some device for better illuminating a finer screen—as a whole or partially—appreciation of the powers of this form of lens at nearer distances would undoubtedly and immediately rise to a high standard. As it is, where there is an object against a sky line the difficulties of focussing are much reduced. The exposure with it is also longer, although at this time of the year at its least long point. The use of a colour screen, obligatory as a rule, to minimise the effect of haze when photographing objects at a distance is unnecessary with objects nearer at hand, and largely reduces the length of exposure. There is a very high charm about a good telephoto picture. It is due in chief measure to the fact that it must of necessity be more of a suggestive part than of a whole. This is proof of our contention as to the artistic higher relative value of a part compared with the whole. Let the thoughtful amateur, equipped with whatever lens he may happen to possess, at least give the principle a trial. He is certain to feel gratified with his results, and at realising in practice some of the artistic possibilities of photography.—I am, yours, etc.,
ELDON.

August 4, 1904.

New Book.

"Leitfaden der Landschafts-Photographie." Fritz Loescher. Verlag von Gustav Schmidt. Berlin.

It is with much pleasure we see that a second edition of this work has been published. The author's object has been to place in the hands of the amateur a book which will be of service to him in the pursuit of landscape photography. We can but confirm the appreciative remarks we made in our issue of July 5, 1901, concerning the excellence of the book in this respect. On the other hand, we think it unfortunate that the author has not revised the remarks concerning perspective published in the first edition, to which we then drew attention. In graphically representing the external world, the most perfect perspective is geometrical perspective. With this the photographer can comply, and his work may be more exact than that of any artist. To introduce the question of "subjective perspective" confuses rather than assists the reader. Concerning the selection of a hand camera, the recommendation of the dark-slide type is probably a wise one, as the author is addressing German readers. Were he acquainted with the best type of English magazine cameras, however, we think that his ideas would be modified, as he would find his criticisms groundless. We have used one of these instruments for many years, and have never had trouble in changing the plates, nor scratches from such a cause. The magazine is detachable, and a screen is provided for focussing in case of need. We may even mention an advantage which this form has over the dark-slide pattern, which we think Herr Loescher will not think unimportant. For twelve plates in dark slides, the twelve frames upon which the plates rest must be in perfect register, but in the magazine we refer to all twelve plates are brought into focus by contact with one pair of stops. With such a magazine, who would be troubled with dark slides?

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.
ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION. Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada,
Half Year	5	5	Australia, Africa, New Zealand, New-
Quarter Year	2	6	foundland, Germany, Russia, Portugal,
			Spain, Italy, Egypt, India, China,
			Japan, &c. One Year ... 18s.

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- JOHN & PAYNE, 9, Lower Sackville Street, Dublin. Photograph of front of Oliver Plunket Memorial Church, Drogheda, showing Cardinals Vannutelli and Logue. Photograph of Cardinals Vannutelli and Logue and Most Rev. Monsignor Segura.
- Excelsior Photographic Company, 17, King Street, Carmarthen. Three Photographs of Twelve Girls in Welsh Costume, entitled, "Merched Llandissilio."
- H. Adamstone, London Road, Mersham, near Redhill. Photograph of a Cricket Match. Photograph entitled, "At the Death of Foz."
- G. C. Fisher, 36, Fore Street, Bridgewater. Photograph of Interior of Agapemone, Spaxton, Bridgewater.
- D. C. Latham, Grove Studio, Station Road, Buxton. Photograph of Cat and Fiddle Hotel, near Buxton.

TINTOMAD.—Messrs. Wyndham and Co., of Acton, will supply the sort of thing you require.

QUERIST.—1. Messrs. R. and J. Beck, 68, Cornhill, publish a book which should answer your purpose. 2. We know of no such work.

J. W. COOPER.—We are much obliged for your interesting letter and enclosure; there is, however, nothing novel in the idea. Nor do we think it of much practical photographic value.

COPYRIGHT.—K. OSBORNE says: "I should be glad if you would let me know for how long the copyright in a photograph lasts?" In reply: The copyright in a photograph lasts during the life of the author, and for seven years after his, or her, death. After the copyright is once registered no further fee is payable.

LICENCE TO PHOTOGRAPH.—J. BLIGH asks: "Am I obliged to have a general pedlar's licence for taking photographs on the beach? Is there a law to this effect? Kindly let me know." In reply: A pedlar's licence will not be required. But we believe a licence is necessary from the local authorities in most places to practice photography, commercially, on the beach.

BOOKS WANTED.—"W." says: "I should be glad if you will tell me if there are any books published on posing and lighting, and the price of same." In reply: Yes, there are several—see the list on pp. 974-5 of the Almanac. The prices are appended. "The Studio and What to do in It," by H. P. Robinson, is a good book, but there are several others.

PROFITS OF BUSINESS.—"X. Y. Z." asks: "Could you tell me if £100 worth of material would turn out £600 worth of work at 12s. per dozen, without waste? My reason for asking is, I am offered a business taking £600 yearly, and they state they save £250 yearly. Rent, £60. Taxes, £17. Do you think this possible?" In reply: We should say that this is possible if the cost of labour is not taken into consideration and the business is economically managed.

SEPIA PLATINOTYPE PRINTS.—R. RUTHEVEN asks: "Can you give me the formula introduced by Mr. C. F. Inston for giving sepia tones on ordinary cold bath platinum paper?" In reply: The formula you refer to is as follows:—(1) Potassium oxalate, 1 oz.; water, 7 ozs. (2) Potassium citrate, 75 grains; citric acid, 120 grains; mercuric chloride, 45 grains; water, 7 oz. The solutions may be used cold and in equal parts. The clearing bath to be used after development is composed of hydrochloric acid, 1 part; water, 120 parts.

ENLARGING.—GREAVER asks: "I am fixing up an enlarging apparatus. I wish to work with an incandescent gas-light, with an electric condenser. Will you tell me what distance I should place the gas from the condenser to get the most even light on screen? Of course I am anxious to get a good even light." In reply: The focus of the condenser is not mentioned. The best way will be to set up the apparatus and then move the light back and forward until the most even illumination is found on screen.

PAPER WANTED.—H. H. AND CO. write: "One of our foreign correspondents informs us that he has seen a description in certain journals, the titles of which he omitted to note, of a photographic paper capable of producing photographs in colour. The name given to the paper is 'Multico,' and it is believed to be the invention of M. de Slavick, an Austrian, and Hezequiel, a German. We should esteem it a favour if you could inform us if the photo paper is obtainable in England, and if so, at what address." In reply: We believe the paper may be had through Messrs. Penrose and Co., Farringdon Road, E.C. Better to communicate with that firm for particulars.

ONE SOLUTION INTENSIFIER.—"PAN" asks for an intensifier requiring only one solution. In reply: The following formula will be found reliable:—No. 1. Mercuric chloride, 12 grains; water, 2 ounces. No. 2. Potassic iodide, 3 drachms; water, 2 ounces. Put No. 1 into a graduate, and add No. 2, drop by drop. As soon as it will become cloudy, but finally clear up again. When it is clear, and add a small piece of hypo about the size of a pea. Pour over the plate and rock until desired density is obtained, then wash for twenty minutes. You will notice that this is not a double process bath, and the plate does not bleach. Instead, it steadily intensifies, and requires no further treatment.

REDUCER FOR BROMIDES.—L. B. ROBERTS writes: "I have several bromide prints that have been over-printed and developed, so that much of the shadow details are lost when the prints are viewed by reflected light, but are visible when seen by transmitted light. I cannot produce duplicates of these prints as the negatives are not accessible. Please, give me a formula for reducing the density of the prints without staining them." In reply: The following is excellent for reducing bromides on developing papers: Potassium ferric oxalate, 20 grs.; sodium sulphite, 200 grs.; water, 5 oz. Shake till dissolved and add Oxalic acid (crystal), 75 grs., and shake till the solution turns bright green; pour off from any undissolved acid, and add Hypo, 2½ oz.; water to 10 oz. For use mix with two parts water.

SPOTTY PRINTS.—ALCO EDWARDS asks: "(1) Will you kindly tell me what is the matter with the enclosed prints? They were developed over-night on the enamelling glass, and were quite right when squeezed down. On coming to take them off this morning they were as you see them. I enclose a piece of the blotting-paper I use. (2) I should be very much obliged if you could recommend a pure stout blotting-paper. (3) Can you also give me the address of the Rotograph Co.?" In reply: The cause of the spots is that the print, or the plate, was splashed with some chemical before the pictures were squeezed upon it. The blotting-paper has nothing to do with the trouble. (2) Blotting-paper suitable for photographic purposes may be had from any of the large houses, such as Marion's and others. (3) The address is 14, New Union Street, Moorfields, E.C. We do not answer correspondents by post.

SENSITISING DRAWING PAPER.—E. D. S. SEYMOUR asks: "Is it possible to prepare ordinary drawing paper so that photographs can be printed on it from ordinary negatives?" In reply: The following will be found an excellent and easy method of sensitising any drawing paper for printing out:—Take arrow root, 1½ ozs.; water, 1½ ozs. Boil until quite clear, and dissolve in the hot solution: Salt, 15 grs.; citric acid, 5 grs. Allow to get quite cold and take off the skin, then, with a soft brush, spread the clear jelly rather thickly over the paper, which should be pinned to a drawing board or other flat surface, and allow to thoroughly dry, then brush over it a solution of silver nitrate, 50 grs.; water, 1 oz.; to which strong liquid ammonia has been added till the brown precipitate first formed has been re-dissolved, then dry and print on it within two days. With platinum toning this will give blackish brown prints.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose continuing the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

*** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that this year's entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st—a fortnight earlier than usual, so as to be well advanced of the Christmas publication season.

EX CATHEDRA.

The Traill Taylor Lecture. We learn from the Honorary Secretary of the Traill Taylor Memorial that Dr. R. T. Glazebrook has accepted the Lectureship for the current year. The delivery of the lecture will probably take place in the course of December next. Dr. Glazebrook's position as Director of the National Physical Laboratory, and his reputation as author of several of the Cambridge Natural Science Manuals dealing with Light, Heat, Mechanics, Hydrostatics and Electricity should cause photographers to make a mental note of the lecture and endeavour to attend.

* * *

An Improvement in Self-registering Thermometers. Though these instruments are less used by the photographer than the physician, there still arise many occasions, manufacturing and meteorological, where the former makes use of them; hence a reference to an improvement recently devised by Mr. Hicks will be of interest to many of our readers. The present well-known form of registering thermometer acts by a constriction near the bulb, permitting the mercury expanded by heat to pass beyond it, but not to return, as the metal contracts and leaves the column in the tube at the highest point it has attained since setting. The setting is made by swinging and jerking the thermometer when cold, so as to jerk the column back to join the remainder in the bulb. Everyone who uses these instruments has at times experienced the annoyance of the difficulty in getting all the mercury back. Mr. Hicks' improvement consists in making the constriction double and wider, and it has been shown, not to enter unnecessarily into the theory, that this doubling of the throttling, with its attendant widening, makes the former troublesome jerking entirely unnecessary.

* * *

Dry-Plate Glass. One of the drawbacks to cheap German dry-plates is the quality of the glass used in their manufacture. Native industry has been encouraged by the imposition of a duty on foreign glass, but from the report of the Dresden Chamber of Commerce the foreign manufacturers, and especially the English, still holds the field. The report for 1903 states that the Lommatsch factory turned its attention to dry-plate glass in the preceding year and found a ready sale at remunerative prices. However, in 1903 Belgian and English manufacturers entered into keen competition. We thank the Dresden Chamber of Commerce for the restrained compliment which follows, that English glass is good, in a moderate degree, and for the frank acknowledgment, that though the Belgian prices are cheaper, the material does not enter into serious competition. But the result of the year's business is still more satisfactory from a British

aspect. The Lommatzsch factory has been compelled to reduce considerably its output of dry-plate glass and produce window glass instead. This means that German dry-plate makers find it more to their interest to use the British article, notwithstanding the duty placed upon it.

The Causes and the Suggested Remedy.

In the report referred to, the Lommatzsch firm gives as a reason for its want of success the difference in the cost of carriage. It reminds us of the complaints made by the English farmer, when he cries out about foreign competition. It is alleged that the freight from England to the principal places of dry-plate manufacture in Germany is one farthing per square metre, but from Lommatzsch, not far from Dresden, it is five farthings. We cannot give exact figures, because we do not know what is the average yield of quarter-plates from a square metre of glass, but assuming it to be one gross, the difference of carriage amounts to less than one-half farthing per dozen. Against this must be set the present import duty on glass into Germany. From these figures it seems doubtful if the difference in cost of carriage is the chief reason for the preference given by German dry-plate manufacturers to English glass, although it may claim their attention. Perhaps the German glass manufacturer has an axe to grind with the State railways, and takes the opportunity to strike a blow, but from conversation with Germans, who know the English shilling quarter-plate, we think the chief reason is the superior quality of the English glass, which generally excites their admiration. The remedy suggested is, of course, an increment of the duty on foreign glass, but the German plate manufacturer might have something to say on that subject, as it would affect their export trade.

A Use for Radium.

Those who have worked at Photomicrography earnestly enough to cut their own sections with the microtome, will call to mind a difficulty which often occurs at the last moment. The section to be cut has been hardened and buried in paraffin wax, and all that remains is to see that the knife of the microtome has an edge as keen as that of a razor, before proceeding to cut the delicate shavings from the mass. Here comes the trouble. The friction of the knife against the paraffin arouses a certain amount of electricity, and this makes the shavings, instead of falling off as they should do, curl up and stick together in the most exasperating manner. Some genius has hit upon the expedient of dispelling the frictional electricity thus induced by the use of radium. We may remind our readers that this rare element, amongst its other curious attributes, possesses the power of discharging an electroscope. To put the matter more plainly, when the two strips of gold, or aluminium leaf, which constitute the electroscope, are charged, they stand out from one another, each repelling its companion. But when a morsel of radium, or a lump of pitchblende containing radium is brought near the instrument, the charge of electricity is dispelled, and the metal leaves fall once more together. The ingenious one already referred to arms his microtome knife with a tiny tube containing five milligrams of radium bromide, and this is quite sufficient to at once drive away the electricity which is aroused by the action of the blade over the paraffin. We have heard so much about radium and the wonders which it is likely to accomplish, including the cure of cancer and half a dozen other diseases, that it is quite refreshing to hear of it being of some kind of real use.

Ruby Glass.

In the early days of the gelatino-bromide dry plate it was quickly seen that, the comparative flood of bright orange light that experience

showed to be harmless to the wet plate during the period of development and quick fixing could not be employed with the new plates without producing irreparable fog. The consequence was the bringing largely into use of ruby glass, often so sparingly as to make illumination of the plate scarcely visible at all. Notwithstanding this, it was found that even ruby glass acting sufficiently long on the film, produced fog. Spectroscopic investigation quickly showed the cause—the transparency of this glass to a certain amount of rays of high refrangibility. When this defect of ruby glass was seen experimenters ran riot in the extraordinary recommendations as to the colour of screens to be used, and this day there is no certainty as to what colour of adiacent medium may not be come across on entering a strict dark-room. At a recent meeting of the Royal Society a paper read by Mr. J. C. Maxwell Garnett contains some interesting references to the matter. At an early stage in the manufacture of the ruby glass it is colourless, and does not attain the well-known colour till the second heating. In this first stage the gold or copper which gives the colour is in a state of solution or combination. After the second heating it exists in the form of minute spheres as observed by Siedentopf and Zsigmundy. In a case of this kind where we have a medium (glass) made up of metal spheres embedded in a non-light absorbing substance and of a distance apart of the spheres, but upon certain optical qualities of the metal of which the spheres are composed and the refractive index of the embedding material, the glass in its colourless stage can be brought to the colour by the radiation from radium. A further point of interest in the paper was the evidence adduced to show that the remarkable coloured preparations of metallic silver discovered by Carey Lea, and termed by him photogenic salts, are examples of this type of medium.

Decaying Leather Bindings.

One of the minor ills of life to which the professional photographer is liable is the rotting of the leather binding of his books, whether his commercial records, works of reference, or bound albums of specimens or registers, that have been stored on his shelves for some years. The defect manifests itself by the backs either coming apart, or becoming so fragile that a mere touch causes pieces to fall away, and render the volumes most unsightly. The evil is not confined to photographic studios; it becomes a most important object of investigation to the possessors of books or their custodians. What the exact cause is has not been definitely agreed upon; probably it is two-fold. First, seeds of decay inherent in the leather employed, through the retention of deleterious agents, mainly acid, used in their manufacture; and secondly, the action of the products of the combustion of gas in the apartments the books are stored in. Nearly all gas contains sulphur, which, after combustion of the gas, enters the atmosphere as sulphurous acid, soon to be oxidised to sulphuric acid, and this, year by year being absorbed by the bindings, increases in quantity till a time arrives when there is sufficient absorbed to decompose the leather. This view has been questioned, but that it is one cannot admit of dispute, as our own experience proves. We possess a gradual accumulation of a number of volumes of a scientific journal, bound in leather, some of which occupied the top shelves in a room lighted by gas, others were on lower shelves. Those on the upper shelves where the gas fumes would mainly act, when they came to be removed fell to pieces. Those on the lower shelves, where less gas fumes had play, were in good condition. The lesson this teaches to photographers having

able records, bound, or "half-bound" in leather is to be careful not to store them on upper shelves in rooms where gas is burned. Some time ago the question was discussed at the Society of Arts, the general feeling being that gas fumes were not the primary cause, but that acids in the process of manufacture was the chief factor in the process of decay. A committee was formed by the Society, and issued certain recommendations as to a suitable mode of preparing the leather. Such leather has now been prepared, and upwards of sixty institutions have been arranged to give it a trial, and report results. These reports, when issued, will be interesting to everyone.

* * *

Lightning. A good photograph, showing all the wonderful ramifications of a complex flash of lightning, makes a beautiful picture and its producer generally values it only because it means the one successful negative of a heap of plates which have been sacrificed in the name of science. Such photographs are of extreme interest to the meteorologist, for they record in a manner impossible by any other means the exact form of the course pursued by the electric charge, whilst any peculiarities due to local conditions are accurately noted. But there is one form of lightning which, so far as we can discover, has never yet been photographed, and the omission is solely due to its rare occurrence. In Ganot's "Physics" a phenomenon to which we refer is thus described:—"There are, further, the lightning flashes which appear in the form of globes of fire. These, which are sometimes as large as much as ten seconds, descend from the clouds to the earth with such slowness that the eye can follow them. They often rebound on reaching the ground; at other times they burst and explode with a noise like that of the report of many cannon." We remember once to have seen a flash of this kind in the North Sea, the globe of light taking about two seconds in its descent. Evidently something of the same nature took place the other day at Portsmouth during a thunderstorm, although it has not been described by one paper as "a thunderbolt," and by another as a meteoric stone. Here is the account as published in the "Daily Telegraph":—"A tremendous flash of lightning was seen, and at the same instant a brilliant electric burst from the clouds and shot downwards into the sea. It fell into Portsmouth Harbour, between the Victory, flagship of Admiral Sir John Fisher, and the gun-crews signalling school. . . . The general impression of those who witnessed the incident was that a meteorite had fallen." Another instance of the vagaries of lightning recently came from America, and it revives the old idea that lightning has the property of printing upon the skin of its victim a picture, generally of the identical nature under which the person chiefly concerned was seeking shelter when he was struck down. Photography has been its best to explain away this apparent mystery. The action of the sudden discharge upon the skin is to draw out the blood of the minute vessels and to make a kind of latent pattern upon the epidermis. This effect has been photographed, and the picture has been published more than once. But pictures, said to present an accurate representation of the surrounding scenery, and printed upon the skin of those struck, continue to be reported. In this latest account from America, the skin pattern is said to be that of a crucifix, and to be regarded by many as a miracle. Possibly later on this marvel may be photographed, and we shall have an opportunity of judging of its merits. If the picture does not come to hand, we shall regard the story as yet another production of the ingenious wonder-monger.

THE PASSING OF THE PEN-DRAUGHTSMAN.

THE art of drawing with the pen has for some years been closely allied with photography, although as every one knows it had some distinguished artists among its professors long before photography brought it into prominence and pushed it forward into a position which it would never have assumed had it not been for the camera and lens. There is every sign that to photography, its whilom friend, the art of line drawing with pen and ink will also owe its extinction, or at any rate its retreat once more within the narrow limits which it formerly occupied. For the larger section of the public, which knows nothing of art beyond what it picks up in a kind of vicarious way during a visit to the Royal Academy with a borrowed and marked catalogue, a public which cannot see the beauty of a curved line, naturally prefers a photograph. And if not a photograph, a wash drawing, which to them is so like the work of the camera that they cannot readily distinguish the one from the other. Fate is on the side of the public in this matter, for out of a hundred artists who can make a presentable picture in monochrome wash, there is hardly one who can arrive at the same result when restricted to pen and ink.

It was a happy day for the pen artist, as it was a fateful one for the poor wood engraver, when it was discovered that by means of the camera a line drawing could be converted into a block, which could give impressions in printers' ink. It was not the first boon that photography had granted to the artist—at least to the artist who devoted his efforts to illustrations for the press. If we look back to some of the early issues, say, of the "Cornhill Magazine," we shall find many illustrations to novels by Thackeray, Geo. Elliot, and others, by Millais, Fred Walker, and artists of a like calibre. It might be reasonably thought that the original drawings from which these blocks were made would be priceless. Or if not quite that, we may be certain that a collection of them would represent a very respectable fortune. But, unfortunately, they do not exist. These artists drew their designs direct on the boxwood block, and in the operation of cutting out the "whites" between the lines, the engraver destroyed the originals. The work of these eminent artists was reduced to tiny chips, which in due course were swept into the dusthole.

It was after this period that the good fairy Photography stepped in, and granted her first boon to the producer of pictures for the press. "Do not draw on the wood," she said, "but on the paper or cardboard to which you are better accustomed, and with a touch of my wand I will transfer your drawing to the wood block, will reduce or increase its size to anything you like, and leave your original work unchanged in every way." This was a gift indeed, and it seemed as if the days of the old magicians had once more come upon us. Possibly at first it benefited publishers more than the actual workers, and it can easily be understood how often it came about that they could sell an original drawing for a good deal more than they paid the artist for it, even after they had drawn a handsome profit by using it in the printing press.

Then the fairy again appeared, and she offered a second boon to the pen and ink artist. "I have already taught you," she said, "how to transfer your drawing direct to the wood block; now I will show you how to do without the wood block altogether." And while the artists were blessing the fairy for her good works, the poor engravers were cursing her as an evil genius. Most of them had been brought up from their youth to the cutting of wood blocks. It was a difficult art, and one which required a long apprenticeship. Beautiful machines, on the principle of the ruling machine, had been introduced to help

the graver in its work, but for the most part it was literally a manipulatory process, this art of wood engraving. And it had been brought to a surprising pitch of perfection. It was no longer necessary for an artist to draw in actual line; he could, if skilful enough, simply tint—that is to say, he could rub his drawing in with washes of Indian ink and Chinese white. The engraver was able to translate these half-tones into line, and would alter the depth of the cut, the pressure of the tool, and the distance apart of the delicate ridges, with every variation of tone presented to him. It was a wonderful art, and its professors did not get half the credit due to them, simply for the reason that the public could only admire the picture, without troubling themselves to understand the methods by which the effects were produced.

As we have said, it was a fateful day when the knell of doom came to the poor wood engraver. One of those sad instances which occur of the individual being submerged for the general good; one of the cruelties of progress, which have to be accepted as a necessity. There were naturally a large number of admirers of wood engraving who mourned the extinction of a beautiful form of artistic expression, and there is no doubt that an effort would have been made to save it, had it not been for the inexorable logic of those three little letters, *£ s. d.* When a block which would cost several pounds to engrave could be produced by photographic process for less than as many shillings, the dilettante had to hold his peace. "It's the money that makes the mill to go," and the cheaper rate at which the machinery can be driven, the more there is for the proprietor thereof. The expense of making these new blocks was so insignificant compared to wood engraving, where very often the engraver claimed as much as the artist, that publishers jumped at them as greedily as a trout will snap at a May fly. Line artists were immediately in demand. Schools for their instruction were established, and journals full of pictures, good, bad, and indifferent, fell upon the world as thickly as leaves in Vallambrosa. Many benefited by the boom, and even the makers of collodion, who when dry plates came to the front found their occupation almost gone, became more busy than ever. The old wet plate process was restored as the best method of making negatives of the necessary opacity for the new system of block production. Every one rejoiced, except the poor engraver, who, unless he had the prescience to turn to zinc and copper as alternatives to wood—unless, that is, he had the pluck to march with the times—found himself in a very bad way.

And so the pen artist had a good time of it, and a few workers came to the front who did masterly work. In a recent book by Mr. Pennell, one of the masters, he goes so far as to affirm that pen-draughtsmanship is the only healthy art developed in the nineteenth century. Certainly it is something which stands apart from all other methods of artistic expression. Every line has to tell, and has to have a meaning. Take, for example, one of Phil May's remarkable pen drawings. It looks as if the lines were thrown together in the most careless manner, but it is well known that this artist made a careful pencil study first, and afterwards worked his pen lines above it. Take away one of those subtle lines from one of his faces, and the loss will be apparent.

Once more the good fairy came to Earth, and it would seem that by this time she had a little changed her mind with regard to pen drawing. Possibly she thought that the boon which she had given had been too lightly regarded, or possibly that the artists were getting too bumptious with success. This time she brought as a gift to art the half-tone block. At first it did the penmen no harm, for two shillings per inch could not compete with fourpence. Besides which, the printers declared that

the blocks were no use; they were so shallow that they quickly clogged up with ink, and were not worth this of seriously. We know now how wrong the printers and how the various difficulties connected with the tone block have been surmounted. Competition, too, stepped in, and competition is so keen that a half-tone block can now be had at the price of one in line. The result is obvious; the drawing in pure line is being discarded for more easily accomplished wash drawings. Photography, which a couple of decades ago gave the draughtsman such a splendid lift, has now dropped again, and he must retire into his old groove. Although we have headed this article in a manner which would indicate his extinction, we do believe that drawing will be valued by those who can really appreciate its merits. Possibly the familiarity with it of its sometime yokefellow, photography, has brought about a will do something to make people understand its beauty, but for the present, at all events, the half-tone block, either from a photograph or a wash-drawing, is in the ascendant.

IS PHOTOGRAPHIC PERMANENCE DESIRABLE?

THE above question should be one of considerable importance to every one who practises photography, whether as a professional or as an amateur. The subject is too frequently neglected by both. It must be admitted that a very large number of photographs are now produced daily that, for the credit of the art, it is by no means desirable that they should prove too stable. There are others in which permanency is a most important consideration—family portraits, to wit—for life is not certain. More photographs are, undoubtedly, now being made daily than at any previous time in the history of photography, and there is little question that a large proportion of them will prove fugitive in the near future than has ever been the case before. With all the knowledge gained, both in theory and practice, during the past forty years and more, is this to the credit of photography and photographers?

The carbon and platinotype processes both yield pictures of undoubted permanence. But need silver prints be as unstable as many persons seem to imagine? We say, no. There are thousands of silver prints still in existence which were made forty, and upward, years ago, that up to the present show no signs of lack of stability. If these could be produced forty years ago, why, with our extensive knowledge of the chemistry of the subject, cannot similar results be done now? It may, *en passant*, be asked how long should a silver print last. Some seem to be of opinion that if it exists for three or four years, that is all that should be expected of it, and it is to be regretted for the credit of photography, that very many do not do for anything like that time, some even show a marked change in as many months. Indeed, we have seen examples of silver prints in an exhibition that, though good at first, showed a decided change before the exhibition had closed.

During the past few years every effort has been made by manufacturers to simplify photography, in reducing the trouble in its working to a minimum. But it is interesting to inquire if this has not, to an extent, been done at the expense of permanency of the results obtained by those who do not fully recognise the principles involved, or, if understood, are neglected.

The old prints that have so well withstood the test of time—the only true test of permanency—were made on plain paper, or on albumenised paper, which the user had to sensitise himself. These papers contained nothing

chloride of silver, with a considerable quantity of the nitrate of silver, plus, in the case of the albumenised, trace of an organic compound of silver termed "albumen of silver." The paper was in a neutral state, and had to be used the day, or day after, it was sensitised. Later on, ready sensitised albumen paper was introduced. This contained an organic acid as a preservative, hence the paper was acid, instead of being neutral as previously. Then gelatine papers, now called P.O.P.s, were introduced. These, in addition to the gelatine, contain chloride of silver, an organic salt of silver, free acid, and only a small proportion of free nitrate of silver. These papers yield very pleasing results, are easy to manipulate, are well suited to the weak negatives of the present day, and, what more, have good keeping qualities. Hence they are very convenient to employ, as well as being economical. For these reasons they have almost entirely ousted the older papers from the field. Where albumen papers are now employed they are usually bought ready sensitised. Indeed, we much doubt if the unsensitised albumen paper is now stocked by any but the larger dealers.

As a further trouble saver, the combined toning and fixing bath was introduced for "P.O.P.s," and became largely used by amateurs, who do not like the trouble of toning and fixing their prints separately. To the use of this bath may be attributed a very large proportion of the fading prints of to-day. Although paper makers, as a rule, give a formula for this bath, they, most of them, discourage its use; yet for all that it is largely used. There is not so much harm in the combined bath if the tones are really obtained by a deposition of gold; but to often the bath is repeatedly used long after its life has been exhausted, as then it will still continue to yield good tones, but they are produced by sulphur toning, the stability of which is more than doubtful. Furthermore, with the combined bath the desired tones are frequently obtained long before the prints are sufficiently fixed, with the result that within a very brief period they develop yellow stains. The latest thing in the way of saving trouble in working is the introduction of the so-called "self-toning papers." These have been too short a time on the market for one to pass any positive opinion as to the stability of the prints made upon them.

One naturally likes to obtain one's results with as little trouble as possible; but, at the same time, is it desirable that this should be done at the expense of their stability? One goes to the trouble to produce a negative that will yield "a thing of beauty," it is desirable that it should be so "a joy for ever," instead of only a fleeting one, even if it should involve a little extra trouble in its production. When commencing this article, we had intended to point out the difference in the conditions of working when the able prints of forty years ago were made and those prevailing at the present time—and they were widely different—but space will not permit. We may, however, recur to the subject at some future time.

DURING these summer and autumn evenings the planet Saturn may be seen rather low down near the southern horizon, about ten or eleven o'clock. The ringed planet is specially interesting to astronomers just now, for he is suspected of having had an addition to his family. Saturn has for certain eight satellites or moons, which have been discovered at intervals between the years 1655 and 1848. In the year 1899 a ninth satellite was reported to be shown by a photograph taken at Harvard College Observatory, but the evidence was not deemed to be conclusive. Lately, however, information given with much confidence comes from America that the satellite has been again seen on photographs taken this year at the same observatory. The ninth moon is excessively minute, so that none but possessors of the largest instruments can hope to see it.

HEDGEROW PHOTOGRAPHY.

As we ramble along through the quiet country roads and lanes in search of pictorial material for our cameras, our eyes are from time to time attracted by some flower growing on the banks, or the movement of some timid retreating animal in the hedgerows that border our path. We pause for a minute to admire the flower, or peep amongst the dry russet and brown leaves that half-fill the shallow ditch by the hedge, to obtain a glimpse of the creature we have disturbed; but there our interest generally terminates, and we wander on again along the road with perhaps a mental note, that upon another occasion we will devote a plate to those groups of hedgerow flowers. Unfortunately the resolution, for one reason or another, is rarely, if ever, carried out, and one of the most interesting environments of the country that the naturalist photographer could wish to find, remains unexplored and neglected.

At almost every season of the year, the photographer will find interesting material in the hedgerows; from early spring until late autumn, so numerous are the subjects and models to be found there, that his only real difficulty will be in making up his mind which to select. The first flowers of the spring are nearly all children of the hedgerow, delicate of hue, sweet-scented, and all too short-lived, giving place with the advancing season and increasing heat of the sun's rays to a more robust and sturdy generation of plants. The vegetation of the hedgerow is of particular interest, for in such a situation the struggle for existence is at its keenest, and affords the most striking examples of adaptation to environment. One of the most interesting and instructive collections of photographs any one could wish to produce would be a series taken throughout the year showing the ever-varying vegetation of the hedgerow.

Although at first one might be led to suppose that photographing the plants of the hedgerow would not be a very serious or difficult matter, actual experience will very quickly prove that it is by no means the simplest or easiest branch of outdoor photography. Indeed, it requires a very great deal more patience and skill than is generally imagined; while if really pictorial results are to be obtained, the photographer must have an artistic temperament and a critical eye for grouping and effective lighting. One of the first, most frequent, and greatest difficulties in photographing the vegetable denizens of the hedgerow, is the constant movement of the plants. Even on the calmest day in summer, when apparently not a breath of wind stirs the foliage, careful watching at once reveals the fact that really the leaves are not altogether motionless for a period sufficiently long to permit of giving a "time" exposure. Therefore, it is of vital importance, if clean, unblurred pictures are to be obtained that the exposure shall be as short as possible.

A hedgerow that crowns a sunny grass-grown bank facing the warm south, generally abounds with bird and animal life, and will yield the photographer an inexhaustible supply of material for his camera. But the birds and animals of the hedgerow are shy, nervous creatures, and many hours of quiet, patient watching and waiting, and the exercise of much ingenuity will be required if the photographs are to be a real success.

All the year round a wonderful variety of bird life frequents the hedgerow, finches, sparrows, robins, thrushes, wrens, and many others; each exhibiting a wonderful degree of individuality of character. Some appear quite bold and friendly, almost desirous of sitting for their portraits; while others are so timid and shy as to be almost impossible to photograph, taxing the patience and resources of the photographer to the utmost. With the advent of spring the courtship of the birds begins, and the photographer will have many a chance of portraying a duel between rival male chaffinches. After the courtship comes the season of nest building, and many a wonderfully constructed nest does the hedgerow shelter. The nest ready for the reception of the eggs, the nest containing the eggs, and with

the mother bird sitting, and later the young fledglings ere they quit the home, all offer material for the photographer.

The animal life of the hedgerow, though not so varied as the bird life, nevertheless will be found of great interest, and to yield a large number of subjects for the camera. The hedgehog makes its winter nest of leaves in a dry cavity at the foot of a secluded hedge; all through the winter it sleeps curled up and hidden away under a warm counterpane of leaves, on the south side of the hedge. As spring advances, and the sun shines with greater warmth, and for a longer time each day, the hedgehog at last awakens from its long winter sleep, which has covered a period of perhaps five or six months, and crawls out of his leafy nest, dazed and weak with his long sleep to bask for an hour or two in the warm life-restoring sunshine.

Other animal denizens of the hedgerow, more picturesque in appearance, are the voles, though the latter are rarely seen above ground. The toad and the grass snake are also to be met with, and these much maligned creatures will be found to yield most quaint and interesting photographs; the toad is a particularly good subject, and if properly treated with gentleness and consideration is a capital model, and will pose *ad lib.* before the camera.

Insect life abounds in the hedgerow, and will keep the photographer busy from spring until autumn. Beetles, butterflies, caterpillars, flies, and spiders, all love the hedgerow and make it their home.

And now a word as to the most suitable apparatus for hedgerow photography. A stand camera with a good extension of bellows is necessary, as a long focus lens is the best type for hedgerow work. A good reflex camera, like the "Birdland," is of inestimable value, as it permits of focussing moving objects up to the instant of exposure, and shows the object exactly the same size as it will appear on the plate. Rapid orthochromatic plates will be found to give the best results all round, and for the "plant-life" of the hedgerow are an absolutely necessity. Given some half-mile of somewhat neglected, wild hedgerow, the photographer will find that he has a happy hunting ground for subjects for his camera, that will keep him busy for many a long day.

F. MARTIN DUNCAN.

ON THE ACTION OF WOOD ON A PHOTOGRAPHIC PLATE IN THE DARK.

[Abstract of a Paper read before the Royal Society.]

It has been shown in former papers that many substances are capable of acting on a photographic plate in the dark and producing a picture of themselves. Further investigation shows that this property belongs probably to all woods, some, however, being much more active than others.

To obtain a picture the wood has to be in contact or at a little distance above the photographic plate, and has to remain there for times varying from half an hour to eighteen hours, and to be at a temperature not higher than 55 deg. C.

The wood of the conifers is very active, and gives pictures which are very definite. Fig. 1 is a picture of a section of a branch of a Scotch fir, and shows well the rings of spring and autumn growth. It is remarkable that the former are very active, producing in this picture the dark rings, and so with the other pictures, the part which is active in the original is dark in the picture. The rings seen in the wood are very sharp and strongly pronounced in the picture. If the action exerted on the plate be owing to the presence of hydrogen peroxide, as has been previously suggested, no doubt it is produced by the resinous bodies present in the wood, but it is remarkable that there is no action from the dark autumn wood. Experiments described in the full paper shows that resin exists in the dark

rings, but apparently under such conditions that it can escape. Other members of the pine group have been experimented with and have been found to behave in the same as the Scotch fir.

With the spruces the action on the plate is not so definite and well marked; the white wood is always active, but in some cases the dark rings are also active, and the pictures are so sharp as with the firs. Larch wood gives a very interesting result, for the picture is the reverse of that of the Scotch fir, that is, the dark rings in the wood are the active rings and light rings are inactive.

With regard to woods other than conifers, oak and beech both active and give very good pictures, so also does ash (*Robinia*), Spanish chestnut, and sycamore; on the other hand, ash, elm, horse chestnut, plane are comparatively but slightly active. In the full paper lists of woods are arranged according to their activity.

Many foreign woods are very active, but as the annual rings are often not well developed, the pictures they give are of somewhat different character. The African black wood, rosewood, cocobola, and many others are very active. Several

Fig. 1.

the foreign woods have a ring of white wood which is quite active.

Knots in a wood generally, but not always, give a good picture. Some of the resin in immediate contact with the knot is in some cases but little active. The marked difference in properties of resins from different sources is described, and it is shown how difficult it is to remove it, so that the wood should be no longer active. Boards that have been exposed to the sun for a long time, an oak box a hundred or more years old, rotted wood from the stump of a tree, and even bog wood have all been found to be still active.

In addition to woods many different resins and allied bodies can, when used alone, be proved to be very active, some naturally much more so than others. Ordinary resins, Burgundy pitch, gum mastic, are very active, asphaltum, dragon's blood much less so, but true gums such as gum-senegal and gum-arabic are entirely without action on a photographic plate.

In certain cases the picture obtained on the plate does not resemble the markings which are visible on the wood. With some woods this more commonly occurs than with others. The picture which is persistent in the wood is shown by fresh sections

ons giving the same result. The true bark of a wood is apparently quite without action on a photographic plate, so is the internal pith of a plant.

There is another and a very interesting action, which occurs with wood, it is the great increase of activity which it exerts on a photographic plate after it has been exposed to a strong light. For instance, if a piece of deal be half covered by black paper or tin foil and be exposed for five to ten minutes to bright sunlight, and then put up in the usual way with a photographic plate, it will give a dark picture where the light has fallen on the wood and only a very faint picture of the part which has been covered. This is shown in Fig. 2. Even comparatively inactive woods such as elm and ivy after a short exposure to bright light give good and dark pictures. The action is not an indiscriminate darkening over the whole wood section, but an intensifying of the parts already active. This increase of activity by the action of light appears to occur with all woods. Artificial light, such as that from the electric arc, or from burning magnesium ribbon, act in the same way, so does even a faint light. A piece of wood put at a window for some

Fig. 2.

hours will give a darker picture than a similar piece left in the middle of the room. This increase of power of a wood to produce a picture does not rapidly pass away. After twenty-four hours the action is visibly less, and decreases more rapidly the first than after some days, but it will be a fortnight or may be a month before the wood resumes its former condition. This action, like the former one, is entirely stopped by interposing the thinnest piece of glass or mica between the photographic plate and the active body. An inactive card painted with an alcoholic solution of resin, acts in the same way, and turpentine which has been exposed to a bright light acts more strongly on a photographic plate than it does when it has not been so exposed. Again, old printing which is now nearly inactive becomes much more active after exposure to sunlight. Bodies other than those which may contain resin or allied substances are not affected in this way by light, for instance, flour, sugar, porcelain; metals are not rendered active by sunlight.

The next point was to ascertain which of the constituents of light was most active in producing these effects, and the first experiments were made by simply placing strips of different coloured glass on wood sections, exposing them to sunlight and afterwards putting them up with the photographic plate in the usual way. Pictures of the results are given in the paper. Red glass entirely prevented any increase in the activity of the

wood, in fact, it acted in the same way as a band of black paper or tin foil would act, and a green glass acted in much the same way, but under a blue glass the activity of the wood was increased to much the same extent as under colourless glass or under no glass. Fig. 3 shows what happens when a red glass and a white glass are placed upon it and is exposed to sunlight. On the right of the figure there was no glass.

Further experiments were made by placing similar pieces of deal in light which had passed through different coloured solutions. Three double-cased bell jars were taken, one was charged with a solution of potassium bichromate, another with copper ammonium sulphate solution, and the third with pure water, and all were exposed to sunlight for four hours. The deal in the red light gave only a faint picture, that in the blue light a dark picture and that with the pure water was only a slightly darker picture. Resin, guaiacum, copal varnish, white oil paint

Fig. 3.

and resin sized paper all acted in the same way and gave similar results.

The light from an arc lamp when passed through a red glass and allowed to fall on a wood section for one and a half hours produced no effect, but when the same light was passed through a blue glass and fell on a similar wood section for only one hour it produced a dark picture. With liquids this same increase of activity by the action of blue light is produced. Turpentine, which has been exposed to blue light is more active than when in its ordinary condition.

W. J. RUSSELL, Ph.D., F.R.S.

AFFILIATION of Photographic Societies.—The executive committee is arranging for a meeting of members of affiliated societies in London during the coming autumn. With the generous assistance of the Royal Photographic Society, this meeting will take place at the New Gallery on the evening of Friday, October 14th, that evening being entirely set aside for the purpose. The committee believe that the members will welcome this opportunity of fraternising and of viewing the 49th exhibition of the Royal Photographic Society, which will be in progress, and that the meeting will do much to foster friendly relations between the affiliated photographic societies. There will be no charge for admission, the council of the Royal Photographic Society having promised free admittance to every member producing his Red Book or the special red ticket issued by the executive committee for the current year. The reception of visitors by the executive committee will commence at 7 o'clock. At 8 o'clock there will be an address by the chairman, followed by an exhibition of the competition slides and slides in natural colours by various processes.

GUM BICHROMATIC PRINTING.

[A Condensed Account of a Demonstration given before the Royal Photographic Society. By Mr. J. C. S. Mummery.]

The gum bichromate process is the most flexible of printing methods. One may exercise greater personal control with it than with any other method of printing, and it has the additional charm that the whole process may, one might almost say must, be carried out from beginning to end by the worker. Any colour may be employed, the prints are permanent, any intensity of deposit may readily be obtained, and the values—the stumbling block of photography—may be corrected or further violated according to the knowledge of the worker. It is the process *par excellence* for those who work for the joy of the work and for those who strive to impart something of their own feeling and sentiment to their photographs.

The process rests upon the action of light upon the bichromates in contact with a colloid substance. It was originated by Mr. Pouncy of Dorchester and, as Pouncy's Carbon process, was published in "Photographic Notes" in 1858. It was laid before this Society at two meetings in 1859, the record of which, in the journal, is very amusing. Pouncy's experiments were possibly based upon the previous work of Fox Talbot, Poitevin and others who had endeavoured to produce a chromic process with gelatine as the colloid, and it is probable that the adoption by Pouncy of the less refractory gum assisted him to obtain his results.

Pouncy produced some very fair specimens which were hardly distinguishable from the silver prints of the period, but judging from the correspondence in the journals of the time, many who tried the process could get no result at all, and some went so far as to say that Pouncy produced his prints by means which he had not disclosed. The process languished, and was pushed aside by the introduction of Mr. Swan's process of carbon printing, which gave a certain and ready method of rendering the exact densities of negatives and could be used commercially. The gum process was unearthed later, and the Artigue paper, which appears to be very similar to gum, was invented in 1889, Mr. Rouillé Ladevéze and others exhibited gum-prints in 1894 and since then it has come into increasing use. The introduction of multiple printing has been of much advantage to the process, giving a depth and transparency hardly otherwise obtainable.

The special materials and apparatus required are suitable paper, gum arabic, bichromate of potash, pigment, brushes, muller and slab, palette knife and actinometer. Almost any kind of paper will be found workable. Mr. Mummery prefers a machine-made drawing paper, manufactured by the O. W. Company of Great Russell Street; it is a hard sized paper which works satisfactorily with the formula given below. Whatman's drawing paper, various cartridge papers—Michallet, Ingres, Allongé—Autotype single transfer and many others work equally well—but for multiple printing a good hard sized paper is desirable if the whites are to be retained. As a rule a soft paper requires a greater proportion of gum, and with a very soft paper it may be necessary to size with gelatine.

Ordinary gum arabic in tears, not necessarily of the best quality, but free from the insoluble gums used as adulterants, should be used. The solution is prepared by placing 4oz. of gum in a piece of linen, tying it up into a bag and suspending it in 12 oz. of cold water in a wide-mouthed bottle. The gum will dissolve in the course of two or three days, and will last a long time. It will become strongly acid, but this is not a matter of much moment; if neutralised with ammonia it will work more freely and give a very fine image, but in multiple printing it seems to have a tendency to reversal and in addition is very much slower in printing. If fungi form upon the stock solution of gum, it is only necessary to filter the solution. Albumen as a substitute for the gum has been tried, but Mr.

Mummery has no personal experience of this modification. The consistency of the gum is an important point, the thinness of the coating depending largely upon this. The bichromate of potash should be in saturated solution.

The pigment should be that obtained from an artist's colour man as levigated powder colour, as this form can be measured better than the moist colour in tubes. Lamp and ivory black, red ochre, burnt sienna, the browns and many other colours are suitable, but sepia and white do not work satisfactorily.

The brushes required are an ordinary camel or bear hair for coating, and a hog hair softener. A piece of ground glass or a muller are necessary for properly mixing the gum and pigment as well as a knife of some sort. An actinometer such as Sawyer's is useful for printing. A board whereon to coat the paper, a sheet of glass or metal to develop upon, and muslin for filtering are also required. The necessity for carefully working by measure cannot be emphasised too strongly; some gum and some bichromate and pigment to taste is an excellent formula for those who hope to fluke a result, but to work the process satisfactorily it is necessary to know what one requires, and to be able to obtain the result with reasonable certainty. The following formula is a kind of standard upon which variations can be made for particular cases:—

Ivory black, 40 grains; burnt sienna, 8 grains; gum (1-3 oz. solution), 1 oz.; bichromate of potash (saturated solution), 1 oz.

This will give a dark warm brown and the proportion of pigment is suitable for double or triple coating. If only one coating be required, the pigment should be increased to 45-50 grains of black and 9-10 grains of burnt sienna. Mr. Mummery does not advocate a large number of coatings; he gets all that he requires in two or three printings. A pigment of a light tint must be used in greater quantity to obtain proper density and a slight increase of the proportion of the gum is desirable. Pouncy, in his original formula, specified 60 grains of lamp black, but this is rather excessive as lamp black has much greater covering power than ivory black.

Black mixed with brown gives the colour most easily worked, and one with which the beginner will get the best results. With some of the other colours there is apt to be difficulty, because of the different exposures they require.

Mr. Mummery then grinds the pigment and gum together with the muller and slab. A pestle and mortar are not adapted for this process, but if a spatula or palette knife be used, the operation takes two or three minutes. The fineness of the result largely depends upon the grinding to which therefore special attention should be given. He then added the bichromate and stirred the mass, afterwards filtering it through two thicknesses of muslin. For single printing one thickness only should be used.

When well mixed a coating on a saucer should appear quite smooth. The sheet of paper to be coated is laid upon a new paper without creases, and pinned to the board. The pigment should be kept well stirred and too much should not be taken on the brush as the essential point of the process is a thin coating. A thick coating peels off, and requires longer exposure. A hog's hair brush, a few inches wide, is useful for working over the paper after the colour has been laid on. This brushing, however, requires to be done very quickly or the coating will become too dry. The brush should not be allowed to "drag" along the paper. If the brush does not pass over smoothly the coating is probably too thick. These details, however, can only be learned by actual experience with the particular colour employed. In the ordinary way, black requires longer exposure than any other colour, and if the coating be at all thick the exposure will have to be prolonged.

The coated paper should lie flat for about thirty minutes to harden and should then be desiccated on the rack over a kitchener or in a cool oven. It is advisable, to lay the paper

a sheet or two of newspaper, so that the bars of the rack do not mark the coated paper. The coated paper is laid flat on a table, because if hung up the sheets will stretch considerably.

Paper coated in this manner will remain workable for some time, even six months, if kept perfectly dry, but it is better to use it within two or three weeks. It is very sensitive to moisture and must be kept in a calcium tube. The coated paper is not sensitive to light until dry; it should be slightly rubbed upon the surface; and an unexposed piece should lose the whole of its coating if soaked in water, a property of preening the paper, introduced by Mr. Packham, is that in which the paper is saturated with bichromate and dried, and afterwards washed with pigment and gum, with water added in place of the bichromate, but no particular advantage attaches to the method.

When multiple coating is resorted to, precaution must be taken to adjust the paper and negative so that they may be placed for the second and following exposures in exact register. An effective printing frame for multiple printing may be constructed with a drawing board, as the base, two fillets of wood screwed at right angles to one another along the edges of the board. The paper is laid upon the board; two strips of board are placed close up to the fillets, the whole being kept in position by means of clamps. The negative is laid upon the top, and on this a piece of thick plate glass. The process is best suited for a thin well-exposed negative with plenty of detail. Good graduations cannot be obtained from a negative made for carbon or platinum printing. Paper negatives may be used in the process, but the exposure with them will require to be somewhat prolonged. Paper prepared as described is better than P.O.P. and will be sufficiently exposed when a negative of Paget P.O.P. shows the depth required in a finished print; such an exposure will be correct for development with ammonia, but for prints to be allowed to develop mechanically a shorter exposure is sufficient.

The chief charm of the print is a certain slight running of the image after development and during drying. Most methods of development by friction, such as brushes, cotton wool, etc., have a tendency to remove too much of the softened gum, and leave the print hard, especially if over-printed. Mr. Packham contrives to have some resistance left in the material rubbed upon, and does not try to get the very last out of it; in development is carried on in this way the colour will run off only a very little. The exposure will be from 2 to 9 tints on the actinometer, according to the colour and density of the negative; a piece of paper mineral at the back of the negative will increase exposure 8 or 9 tints. In a properly exposed print the image will be clearly visible by transmitted light; it is necessary to keep the print absolutely dry if development be hurried, or it will rapidly become insoluble and heavy, and for the same reason a print should not be left longer than is necessary in the printing frame. The "continuating action of ammonia" experienced in the carbon process occurs also in this process after the paper has been exposed, and development should be carried out as soon after the printing as possible.

A variety of methods are available for the development or washing up of the image. The print may lie face downwards in water and develop itself; the image may be washed up under a spray of water, or by laying with water, and an excellent method is with a washstand as used in the Artigue process; this is very useful for high surfaced papers, or, again, a soft brush or pledget of cotton wool may be used either under or above water. The ordinary spray as used for fixed drawings is perhaps the most convenient method as it gives either a delicate or powerful washing at will, according to the distance of the nozzle from the print and the pressure of the air. It may be used either with the bellows with which nature has provided us, which maintain a pressure of nearly 4 lb. to the inch, or with one of

Fletcher's bellows giving a pressure of about 2 lb. per inch. Although the latter requires less effort to work, it is not so delicate or so much under control as the breath. If the high lights come away from the paper in development, it is probable that too much gum has been used in the coating.

The double coating process enables one to intensify all the darker tones, or such as may be desired, and the object of multiple coating and exposure is to get finer graduations in the finished print. It is not necessary that a second or third printing should be of the same duration as the first. The first printing should be longest, the second rather less, and, if a third printing be necessary, it should be still less than the second.

In order to work upon the print with a brush it is desirable that the print should be first dried or nearly so; although a better plan is to entirely dry the print in the dark and wet it again, when the brush may be used with safety. For spotting, the best colour to employ is pigment like that used in coating the paper. Details, such as the clouds, worked in at the first coating, will not be obliterated by a second coating of colour. With regard to fixing the print in the ordinary way this is not necessary. Fixing is simply the removal of the bichromate, and the print is quite permanent when once exposed to light for a time. When using colour such as ivory black and burnt sienna it is not necessary to remove the bichromate of potash, but if it be desired to take out the bichromate, this can be done with a five per cent. solution of alum or a five per cent. solution of bisulphite of soda. Some colours necessitate the removal of the bichromate after development. The prints should not be laid flat to dry or the colour may run into the whites. The best way is to lay the print on a support in a slanting position, keeping the darker portions at the bottom. Alcohol flowed over the print may hasten the drying, but gum prints when wet are so delicate that great care is necessary, or the pigment will leave the paper in a sort of wave. The prints may be varnished either with gum solution or ordinary paper varnish, but before varnishing it is necessary to size the paper with ordinary size or isinglass. Aqueous mountants, such as starch paste, may be used for gum bichromate prints, but Higgin's photographic mountant is a very convenient article for the purpose.

J. C. S. MUMFORD.

No. 1 of the Journal of the Röntgen Society has recently been issued. The editor is Mr. J. H. Gardiner, F.R.S., who has secured the co-operation of many well known investigators interested in the study and discussion of X rays and allied phenomena in their relation to medicine, the arts and sciences, published at 19, Hanover Square, W. The number before us is an excellent production, the literary matter and illustrations bearing on the various applications of the X rays, being of high scientific value.

The arrangements for the annual meeting of the Society of Chemical Industry, which is to take place in New York from September 7 to 12 next, have now been completed. The president, Sir William Ramsay, K.C.B., F.R.S., is to give an address in the gymnasium of the University of Columbia on September 8, and in the evening of that day the annual dinner of the society will be held at the Waldorf-Astoria. A tour has been arranged, to last from Monday, September 12, until Thursday, September 29, with the object of affording members and guests an opportunity of attending the international congresses in St. Louis during the week beginning Monday, September 19. Among the cities to be visited in the course of the tour are Philadelphia, Washington, Pittsburg, St. Louis, Chicago, Detroit, Buffalo (Niagara Falls), and Boston, the last-named to be reached on Thursday, September 29. Ninety-four persons, in addition to those resident in America, have already signified their intention of attending the meetings. Further particulars may be obtained from the general secretary of the society, whose address is Palace Chambers, 9, Bridge Street, Westminster.

A SIMPLE METHOD OF CORRECTING LOCAL DEFECTS IN NEGATIVES.

THE following method of correcting local defects in negatives has for its basis the well-known valuable staining action of anilin dyes. It is described at length in a recent number of "Camera Craft," by Bernard C. Roloff, and the idea is to use a certain dye which has been found to serve the purpose best, and stain the film of the negative at the portions desired. To achieve this result successfully, it is necessary to make a number of applications of a weak alcoholic solution of the dye.

The dye found to be most suitable for this purpose is the red, which may be procured at any drug house. Other dyes, such as orange or yellow anilin, may be used, but the first mentioned is the one which gives the most uniform results. The solution should be as follows:—

Solution A—alcohol (wood), 2 drams; anilin, red, 3 grains.

Solution B—alcohol (wood), 2 drams; anilin, red, 5 grains.

Weaken with $1\frac{1}{2}$ drams alcohol, if too strong.

Ignore sediment, if all the dye does not dissolve.

This produces a somewhat weak solution, but it is not advisable to have the colour strong enough to give a dense stain, as this would defeat our object, viz: a gradual stain, which is barely perceptible at the edges, and which shows no line of demarkation at any point. This latter requirement depends upon the skill and ability of the worker, but by following these explanations and directions any one will be able to apply the stain successfully in the most approved manner.

To apply the solution, use a piece of very soft cloth, perfectly lintless, instead of cotton, which latter, no matter how pure and soft, always leaves a stringy trail of fine particles of lint behind it. All the work may be done in broad daylight, for the light has no appreciable action on the stained film, so that the negative may be taken right before a window and set up at an angle of about forty-five degrees (as in retouching), with a sheet of white paper under it to reflect the light through the negative. The negative, however, should be set solidly so that the circular motion used to apply the stain will not move it, and possibly cause a smudge or stain where none is desired. Having secured it in place, the cloth is now dipped into the weak alcoholic solution (A) of stain and applied directly on to the dry negative on the portion it is desired to stain, care being taken that the circular movement used be very light, no pressure being necessary at first. The first application should entirely cover the part to be stained, with one movement clear to the edges, while the next and following applications may be carried on nearer the centre of that portion. (The last applications may be made with the stronger solution (B), if necessary.) Continued applications are made in the above manner until the stain becomes visible to the eye and your judgment will aid in determining whether or not enough has been applied. The solution being an alcoholic one, the stain rapidly dries, and in a very short space of time, the negative will be dry enough to make a proof to determine exactly if enough stain has been applied. If, by accident, or ignorance, too much has been applied, a solution of alcohol laid on in the same manner will remove as much as is desired.

Before staining is commenced, it would be well for the worker to make a print of the negative, so that a comparison may be made between that and proofs made after staining.

We will suppose that our negative contains good detail and proper gradation in the foreground, but the sky is too dense, although we know that clouds were there when the picture was taken. It is only necessary to stain the landscape portion, and if the stain extend over the edge on to the sky portion very slightly, it will not matter (unless the stain at this edge be too dense), it being sometimes preferable to have the sky darker near the top than at the horizon, as it appears in reality. Practice

makes perfect, and although anyone will be able to do a "stunts," such as staining the landscape portion of a negative, allowing the sky to print darker as just described, yet, on trying a few times on waste negatives, the amateur will be surprised at his own dexterity in "doping" in clouds where absolutely no detail existed, staining a face in a portrait negative that prints dark, or in securing detail in any desired portion of a landscape negative (if the detail be there), by staining the other portion.

It is an easy matter to correct a hypo stain, no matter irregular it may be. Many of us possess such negatives and print always appears in a lighter shade at the portion affected by the hypo stain. This is corrected by staining the negative (while dry), all around the stained portion, until a proof print no longer shows the difference in density.

It will be found that a thin negative may be greatly improved by this staining, either by staining the entire surface, if underexposed, or, if the thinness be from over-exposure and underdevelopment (and it is not desirable to intensify in the same manner, and then reduce), by staining all but the high light thus giving the needed contrast in a most delicate manner, and if this be carefully done with a solution properly prepared, too strong, the print will show absolutely no sign of "doctoring." The method, however, refers more particularly to printing skies, restraining portions which it is desired to print dark, and correcting the appearance of hypo stain, and a trial will certainly demonstrate its extreme value for these purposes.

THE RÖNTGEN SOCIETY: ITS PAST WORK AND FUTURE PROSPECTS.

[Abstracted from an article in No. 1 of the "Journal of the Röntgen Society."

At the end of the present session the Röntgen Society will have completed its seventh year, a period which seems to furnish a suitable opportunity or reviewing the work it has done and taking a glance at its probable future. It will be convenient to remember at the outset that it was in December, 1895, that Professor Röntgen made his announcement at Würzburg, that in working with a Crookes tube he had observed certain rays which produced results unknown to him at the time, and that, as he was unable to define the character of these emanations, he proposed to call them "X rays." This announcement, it will be remembered, excited the whole scientific world. Physicists in all countries set themselves to investigate these strange phenomena, photographers who had the necessary apparatus commenced to take radiographs, and medical men encouraged by the physicists and photographers to persevere in their work, so that the results obtained might be used for the benefit of humanity, by assisting in the diagnosis, from the exterior of the body, of injuries and diseased conditions which it had only been possible before to reach by the use of probe and scalpel. The year 1896 seems to have been spent in carrying on experiments and further investigations in the subject, which was now growing in universal interest. At the beginning of 1897 it appears to have suggested itself to the minds of a few medical men that it would be well to found a Society for the systematic study of the new phenomena and the turning of the radiations into practical use.

The first definite record I can find of this movement was in March, 1897, when a meeting was held at 20, King William Street, Strand, which was attended by Drs. Fenton, Harrison, Low, and Walsh, Dr. Low presiding. These gentlemen seem to have previously consulted their friends on the subject, for I find that letters were read at that meeting from gentlemen approving the scheme, who regretted their inability to be present. Dr. Walsh was appointed temporary Secretary, and he was instructed to write to prominent members of the medical profession, asking if they would join a Society for the study of the X rays if one was formed. Another meeting was held on April 2, 1897, which was more largely attended, and at which it was unanimously decided that a Society should be formed for the study of the X rays. The idea at first appeared to be to confine the membership to the medical profession, but at this second meeting a draft of proposed rules was drawn up which it was decided to

submit to a large general meeting, together with the recommendation that the Society's basis should include non-medical members, and a sub-committee was formed at that meeting for the purpose of approaching a prominent scientific man, with the view of inviting him to be President. It is interesting to note that our late treasurer, Mr. Thomas Moore, took a prominent part at this and subsequent meetings. At a later meeting it was announced that Professor Silvanus P. Thompson had accepted the presidency, and was also decided that the name of the Society should be "The Röntgen Society."

It must be noted here that, though the basis of the Society was widened so as to include all those taking a scientific interest in rays, it was also thought it might be desirable to form a medical section to deal with matters necessarily excluded from discussion before a mixed audience. This is seen in a report published in the "British Medical Journal" of April 10, 1897, as follows:—"At a meeting of medical men interested in the X ray, held last week at 11, King William Street, Strand, rules were drawn up, subject to final approval at a large general meeting, on the lines common to most scientific societies. It was resolved that membership should not be restricted to medical men, but should include all who are interested in the scientific study of the Röntgen rays. The difficulty of discussing medical matters before a mixed audience will probably be got over by forming a medical subsection. Any inquiries may be made of the Honorary Secretary, Dr. Walsh, 5, Pump Court, Temple, E.C." It is worthy of note, also, that at one of the earliest meetings of the Committee the Secretary was instructed to report both to the lay and the medical press. In order to show the wide basis on which the Society was founded, I ask you to note that in the first list of Vice-Presidents and Members of Council exactly one-half consisted of medical men, and the remainder were laymen representing general physics, electricity, and photography. This is not to be wondered at, because up to that period few medical men had made a special study of electricity, and scarcely any of them possessed the necessary apparatus—such as a large induction coil to carry on the experiments—while a large number could not possibly have the time for the necessary investigations; they therefore sought their scientific friends, and invited their help and co-operation, which was most readily given, and the meetings of the Society testify to the mutual work and co-operation of the lay and medical members.

I particularise this point just now because it has recently been suggested by some, who have not grasped the spirit of the Society, that the lay members have desired to invade the province of the medical man. Nothing could be further from the truth, and I am quite sure the majority of our medical members would bear testimony to the fact that the lay members have always been willing to render them any assistance without obtruding on their special functions. I do not wish to press this point unduly, but before leaving it I would remind you that the action of electricity on the body and its functions is principally physiological. Some of the most eminent physiologists have been laymen, and it is largely their discoveries that we are indebted for the principal part of our knowledge on this important subject. The names of D'Arsonval, Röntgen, Tesla, etc., will at once occur to you in this connection. I would here say that, when the subject of the formation of the Society was first mooted, there were some of us in the scientific world, myself among the number, who hesitated to agree to entertain the proposition, because we felt that there were no many societies already in existence, and that the work of investigating the phenomena of X rays might well be undertaken by some existing society—e.g., the Physical Society. It was soon seen, however, that the facts connected with the subject and the results obtained, were so numerous as to call for continuous attention, and that no existing society could spare time from its ordinary work to give the necessary attention to the new phenomena, around which public interest grew with enormous rapidity.

I think, therefore, there were good grounds for the formation of our Society, and I believe I shall be able to show by its record of work that it has justified its existence. The first general meeting of the Society was held at the rooms of the Medical Society in Chandos Street, Cavendish Square, on June 3, 1897, under the presidency of Professor Silvanus Thompson, and I find that in the course

of some most interesting remarks he said, "the position of the Society was between those devoted purely to medicine, to physics, to photography. In themselves they focussed a number of interests provided for by no other existing bodies, such as, for instance, the Royal Society, the Physical Society, the Photographic Society, and the Institute of Electrical Engineers." The formal inauguration of the Society took place at St. Martin's Town Hall on November 5, 1897. There was a very large attendance, and Professor Silvanus P. Thompson, F.R.S., the President, gave a most brilliant address. Many distinguished men attended including Sir William Crookes, Dr. J. H. Gladstone, Earl Crawford, and Dr. Ferrier, and the exhibition of apparatus and radiographs was full of interest, and bore ample evidence to the value of the work which had been done in the short time since Professor Röntgen called attention to his discovery, and of the immense interest it had excited.

In a short editorial in the archives for February, 1898, the objects of the Society were succinctly stated to be—

1. A study of the nature of the rays.
2. A practical inquiry as to the best apparatus for their production.
3. An investigation of all details bearing on their useful application.

So much for the foundation and constitution of the Society; and now let us look for a short time at the work it has accomplished.

I find, on looking through our archives, that there have been some sixty papers read before the Society since its foundation, besides the valuable presidential addresses. There have also been exhibition meetings each year and evenings devoted to discussion. There must be included with the work of the Society the valuable addresses delivered by the presidents in their respective years of office: Professor Silvanus P. Thompson, Mr. C. W. Mansell-Moullin, Mr. Wilson Noble, Dr. Macintyre, Professor Herbert Jackson, and Lord Blythswood. Then, in each year there has been one evening set apart for discussion, and another for the exhibition of apparatus. I think this shows that a very creditable amount of valuable work has been accomplished by the Society since its commencement.

In estimating the value of the work done by the Society, it is only necessary to compare the X-ray tube and the radiograph of to-day with those obtainable seven years ago. Among the greatest improvements in the tube must be reckoned the introduction of the feature which gave it the name of the "focus-tube," for which advance our late eminent president, Professor Herbert Jackson, was largely responsible. The tube competition, under the presidency of Dr. Macintyre, did a great deal, also, to accentuate the points where improvement was desired in the manufacture of tubes. The exposure necessary for a good radiograph at the present time is only a fraction of that which used to be required in the early days, before X-ray plates, and apparatus were improved, while instruments for the therapeutic application of ultra-violet rays and high frequency have been made and largely improved by members of this Society.

Before leaving this part of the subject, dealing with the constitution and work of the Society, there is just one thing more to record. As soon as the various radiations with which we deal in this Society became known as powerful therapeutic agents, it was obvious that the methods of their application would principally interest the medical members, and it was soon seen by them that the discussions connected with the use and application of these rays involving the treatment of patients could not, in accordance with medical etiquette, be brought before a mixed audience. The matter was laid before the Council, and, with the consent of the members, a new rule was made, under which the medical members could have special meetings whenever they required them for discussions. Since that time no strictly medical subject has been brought before the general meetings, and though the medical members have not made large use of their privilege yet, it is gratifying to note they have made a commencement, and that this evening a paper has been read which could not have been discussed in general meeting. No better evidence could be afforded of the good feeling prevailing in the Society, nor of the regard in which the lay members have always held the medical profession, than the readiness with which the members agreed to the necessary alteration of rules to accomplish this object, by which the medical members really obtained greater privileges than those accorded to the other members of the Society.

We now come to the final part of my subject—the future prospects of the Society. Let me at once say I claim no prophetic

instinct, nor do I propose to indulge in speculations; the question I wish to consider is, "Is there work left for the Society to do?" I cannot answer this question better than by quoting rather largely from the two valuable presidential addresses delivered by Professor Herbert Jackson. In that delivered in November, 1901, he made these pregnant remarks:—

"I hope there may be some opportunity during the coming session of discussions connected with this part of the subject, out of which we may reasonably expect fresh hints for research and for further investigation of the relation of X rays to light, and to those interesting 'Becquerel rays,' which seem, from their behaviour as regards refraction and polarisation to come midway between X rays and ordinary light." After a certain time has elapsed since a new discovery has been made, and when the discovery has been followed up by many enthusiastic workers, it is often by no means unprofitable to return to first principles, and to pass in review the facts which had been gleaned, and to ascertain how far they help us to realise similarities between the phenomena under investigation and others of a kindred nature. The recognition of such similarities is often of the greatest service in interpreting results and in suggesting new lines to work upon. Such a review, in the form of discussion among the members of this Society of the relation between the phenomena connected with X rays and those of light and electricity, might well be of help at the present time, when some generalisation which may serve as a working hypothesis is much wanted.

"Turning to the medical side, I am dealing with an aspect of the subject of which I have no official knowledge. There are, perhaps, hardly any subjects of which it can be said more truly than of medical subjects that silence on the part of a layman is best. Therefore I have no intention of entering into such details as can only fitly be discussed by medical men themselves. Those who have had the opportunity of practical experience in the application of X rays, and who have had the time to carefully study the history of cases subsequent to such application, are alone capable of forming a critical opinion of the value which the rays possess as a therapeutical agent. The first object of the Röntgen Society is to further the knowledge of the employment of X rays in medicine by medical men, and it is highly desirable, in justice to the founders of the Society and in view of the great importance of the subject, that this main object should be constantly kept in mind. Whether as a means of treatment or for diagnostic purposes, the application of X rays and their employment in these directions should be left in the hands of medical men, who alone have the knowledge and experience required to allow of their forming judgments and of recognising and avoiding possible dangers. While, however, the treatment of individuals and the study of the effects upon them must remain with members of the medical profession, they would, I believe, welcome the results of any work which would help them in their own special branch. . . .

"If the importance of studying the results obtainable from X rays along with those from light, electricity, and no doubt also heat, be admitted on the physical and chemical side, it must appeal still more strongly to the members of this Society from the medical side, which, I would emphasise by repetition, represents its main function. I must not allow myself to indulge in speculative generalisations from the published results of the therapeutic value of X rays, light, and electricity, and I have not seen enough to permit me to make any remarks from my own experience; but I think I may venture to say that there are elements in common between the various effects on the animal body sufficiently strong to point to the growing necessity of studying them together and of devising further experiments on simple organisms in which the actions of rapid oscillations from all the various sources should be made the object of researches to endeavour to ascertain what changes in one and the same single cell can be brought about both immediately and in its life-history. . . .

"In the course of such discussions ideas will arise, and in the Röntgen Society there should be no difficulty in finding present members, and, let us hope, new members, anxious and willing to carry them out. Negative results will, no doubt, often ensue, and these would be of value in saving useless waste of time on the part of others; but there is no need to anticipate a preponderance of these. The field is a large one, and has not yet been so cultivated as to show even the faintest sign of exhaustion.

"I definitely, then, suggest to the Society the reconsideration of its constitution and its objects, with a view to modifying them some-

what in the manner which I have endeavoured in a very general way to indicate. Throughout what I have been saying I have had in mind the idea of a Society, composed of medical men and other meeting together to discuss propositions and ideas for original investigations, to communicate and exhibit to one another the outcome of these investigations, and to describe and discuss the results of experience. That the Röntgen Society has fostered this idea with satisfaction to its members I believe, but I also believe that if satisfaction is to be continued the Society must be prepared to considerably widen its sphere of activity."

And in his address of November, 1902, he concluded as follows:—

"Before I conclude I would like to offer a few suggestions, partly as a summary of what has gone before, and partly as an indication of lines along which profitable work might be done. Any suggestion made in an address such as this are bound to be incomplete and bare of details. Filling in the details is a matter for other and less formal meetings than the present. So far as our experience goes, it seems probable that in many cases at least the effect upon living organisms of the agents in which we are specially interested is to increase metabolism. It is highly desirable that some fairly simple experiments should be carried out to ascertain whether, and to what extent, evidence can be obtained of an increased output on the part of animals under the influence of these agents, of such substances as carbon dioxide, and such nitrogen compounds as urea and uric acid. A comparison in this respect of the effects of X rays, light, and high frequency currents, carried out with due regard to measurements of the energy expended and to the time of operation, could hardly fail to afford interesting results, of value to the practitioner. In such experiments it is, of course, necessary to eliminate as far as possible the influence of coincident rise in temperature; but by careful control experiments this would probably be found by no means impossible. Dealing with the same question of metabolism, one is led to a study of the behaviour of simple forms of life, and it would, I think, repay investigators to institute experiments directed to the end of ascertaining the comparative influence of the agents in modifying or accelerating the life-history of unicellular organisms.

"The influence of light upon cell division and upon conjugation have been studied to a considerable extent; but I do not know of any published work dealing in this respect with X rays and electric oscillations of high frequency. If only to fix some limits of overstimulation, it would be well worth while making experiments in this direction. The cleavage of carbon dioxide by plants and the manufacture of starch might with profit be studied while the plants are exposed to the influence of X rays and electric oscillations, to ascertain whether any parallel can be found between their effects and those of light. . . .

"Leaving living organisms, there is a good field for investigation in the process of fermentation. What effect, if any, and what kind of effect, the agents we are considering would have upon the action of enzymes in promoting the hydrolysis of fermentable substances is so far as I am aware, hardly in knowledge at present. A good example to experiment upon would be the behaviour of diastase upon starch and it would be most instructive to learn the comparative effects of the agents in hastening or retarding the conversion of starch into sugar, and to ascertain the relation of the effects, if any, to the intensity of the stimulus applied. Dealing with less complicated material still, there is a wide field for investigation in the possible influence which the agents might exert in bringing about polymerisation among certain classes of carbon compounds, or in effecting the cleavage of existing polymeric bodies. A comparison of the kind and extent of influence exerted by the three agents upon such substances as some of the cyanogen compounds and certain of the aldehydes, taken, for example, might lead to results of much value, even if these results proved to be negative in most cases; for it is essentially desirable to find some measure of the order of magnitude of the changes effected by those agents, and of the nature of the material which can be influenced by them. . . .

"In conclusion, I would emphasise what I said at the beginning of this address, and point out again the richness of the field of work which the Röntgen Society, by enlarging its sphere of activity, has opened up for its own special cultivation. There can be, I think, no doubt, bearing in mind the increasing importance of the medical applications of X rays, light, and electricity, that the inclusion of the study of the two latter agents, which are so closely connected

X rays, was a vital necessity in a Society which was avowedly devoted to the study of the properties of these rays mainly from a practical point of view."

I make no excuse for these lengthy extracts, because they contain words of wisdom spoken by a man who had the clearest insight into the work of this Society, who knew all its bearings, and who was capable of estimating the requirements of medical men as he was of knowing the extent of the assistance which might be expected from earnest students into the nature of the various emanations with which we deal.

J. J. VEZEY, F.R.M.S.

PICTURE POSTCARDS.

In which way we will, picture postcards meet us at every step, and in bad, and indifferent are to be seen in every other shop; but even going into account the millions produced and sold, I do not think of "East Anglian," in "Photographic Scraps") photographers made the most of the demand. No doubt many have sold their plates to publishers, for reproduction in one or other of the magazines, but it is perfectly feasible for every photographer to print and sell local cards, and it would pay well. Real photographs are appreciated by the better class of customers who are tired of the common printed cards, of which thousands can be purchased for a few pence like their own. In addition to this, new views are constantly being made. A customer will not buy the same view again and again, and this is where a professional or amateur can score, as it will only the publishing firms to reproduce a very large quantity of a view, while from one's own negatives few or many can be printed as they are required. For any one going in for the work a few hints will be of service.

First, then, the plates. Of course, two or three sizes may be used, but half-plates have naturally been most generally adopted, but I do not certainly advise the new postcard-size plate, as so much time is lost in the printing. Ilford plates are supplied in this size, $5\frac{1}{2}$ by $3\frac{1}{2}$ in., in all varieties, and I have lately been using them in Special Development, with the greatest advantage, as the lens can be stopped down, and yet very quick shutter-exposures be given. It should be remembered that nothing goes down with the general public but bright views. Carriers are used in the half-plate slides, and the printing-screen is matted to the size. The view is arranged accordingly, only just what is wanted is taken on the plate, and if a postcard size ($5\frac{1}{2}$ in. by $3\frac{1}{2}$ in.) is used, the card may be dropped into the frame closed at once, and when printed will come out with a white border, without any further trouble.

Picture Cards.—These are now made in all varieties. Ilford P.O.P. and self-toning both matt and glossy; gaslight, and ordinary. Workers can, therefore, choose those best adapted to their various methods. If the day can be spared for printing, no doubt P.W. will be used. I had a prejudice against self-toning papers for some time, I think because I tried a bad sample of a paper (not P.W.) when it first came out, but I have lately printed some Kalona and am delighted with it; the sulphocyanide bath is no trouble at all and gives a beautiful tone results.

For quickness, however, the "Gaslight" must be preferred to P.O.P. and a few seconds to daylight inside a room, behind a window covered with tissue paper; the light is diffused and very even. I use two boxes or drawers, one to hold the unexposed cards and the other those that have been exposed. I make a test exposure, at a small distance, say, six inches, develop this at once, and if satisfactory, I forthwith mark on the edge of the negative, G. (for Gaslight) and 6 sec. at 6 inches, so that it can be immediately repeated, or if the negative is not required again for several months, I have only to place it at it to know the proper exposure. A similar mark in another corner will register for bromide printing; and, of course, these particulars will serve for bromide papers as well as for postcards. If the exposure is made by gas, which will answer exceedingly well for an amateur, but takes too long for a professional, put a piece of fine ground-glass into the frame first, and then the negative. This works for all bromide printing, whether gaslight or ordinary, except in a very dense negative indeed; it saves many a weak one.

Developer.—If familiar with bromide work, by all means use the same you are used to, but if you are beginning, follow the Ilford

instructions, which are enclosed in each packet of postcards. For myself I use just a little stronger formula, which suits my method of working, and I therefore give it, as some may like to see whether it suits them as well:—

Metol	20 grains.
Hydroquinone	60 grains.
Sodium Sulphite	$1\frac{1}{2}$ ounces.
Sodium Carbonate (crystals)	$1\frac{1}{2}$ ounces.
Potassium Bromide	10 grains.
Water to	20 ounces.

Dissolve the metol in 8 oz. of water and the sulphite of soda in 10 oz. of water. When the latter is dissolved, add the hydroquinone, then the carbonate of soda and the bromide, finally add the dissolved metol, and make up to the 20 oz. Use as given for Gaslight paper or postcards and for bromide postcards. For bromide paper dilute with an equal quantity of water. This keeps well and, for the bromide paper, may be used over and over again, in fact, I do not add any fresh, if the quantity is sufficient, whether I do two, or two dozen pieces. With "Gaslight" it is different, this must be brought up quickly to give a good colour.

When developed, plunge straight, without any washing, into hypo, which is made up as recommended by Chapman Jones:—

Hypo	1 lb.
Water	80 ozs.

Add

Carbonate of Soda	$\frac{1}{4}$ oz.
Sulphite of Soda	1 oz.

Fix at least ten minutes, with the cards well under the solution. Wash as usual. For those who have no proper washer, I would advise the use of a large white enamelled kitchen bowl. Stand this under a tap with a piece of rubber pipe about eighteen inches long attached to it. Let the stream of water play in a forward direction upon the side of the bowl; this will give a circular motion to the water, and the cards will go gently, or fast, at will, round and round; keep them separate from each other, and twenty minutes' or half-an-hour's washing should be sufficient. I then lay the cards on a board covered with a clean, soft linen cloth, and if they should happen to be a little curled when dry, a few strokes with a paper-knife on the backs will soon put them right.

THE LATE ALEXANDER TATE.

MEMBERS of the Photographic Convention and many other readers of the Journal will regret to learn of the death of Mr. Alexander Tate, which occurred on the morning of the 29th ult., at his residence, Rantalard, Whitehouse. To his immediate friends the announcement, writes the "Belfast News Letter," will not come altogether as a surprise. For some time past he has been in failing health, and the weight of years—eighty-one—told heavily on him. Still the end was not expected so soon. He was able to go about, and so recently as the 28th ult. he enjoyed a walk in the open air. On the following morning he passed peacefully away in his sleep. During his illness he was attended by Dr. Manly. The late Mr. Tate, whose father was a resident of Dublin, received his early training as an engineer and architect under the late Mr. Owen, Commissioner of the Board of Public Works. He had as a fellow pupil the late Sir Charles Lanyon, and in his studies he displayed that intuitive faculty and grasp of detail which afterwards enabled him to succeed so well in his profession. When quite a young man he was appointed surveyor of a division of County Dublin, and this position he filled with marked ability for many years. Towards the end of 1861, upon the resignation of Sir Charles Lanyon, he was elected to the important office of surveyor of County Antrim and the County of the Town of Carrickfergus, and he then came to live in Belfast. For over twenty years he acted in that capacity, and under his supervision many important schemes were carried out. About 1884 he resigned the surveyorship of County Antrim, being succeeded by Mr. John H. Brett, and a year or so later he retired from the position in Carrickfergus. Since then he had not engaged in active work, so far as his profession was concerned, but if released from public service he by no means allowed time to hang idly on his hands. He was always interested in scientific research, and was a leading member of various societies. Among the number may be included the Belfast Naturalists' Field Club, the

Royal Society of Antiquaries in Ireland, the Institute of Civil Engineers of Ireland, of which he was the hon. secretary when in Dublin; the Royal Society of Dublin, the Photographic Society, the British Astronomical Association, and the British Association. In connection with the last-named body, of which he was a life member, he acted as secretary of one of the sections when the association met in Dublin in 1857. Technical education found in him a warm supporter, and he was prominently identified with the old Government School of Art before it was merged in the Municipal Technical Institute.

New Book.

Picture Titles for Painters and Photographers. By A. L. Baldry. Pp. 284. Published at the Offices of "The Studio," Leicester Square, London.

The list of Forthcoming Exhibitions, printed in another part of this Journal, testifies to the fact that the photographic exhibition season starts practically from the date of writing, and continues until the end of next June—a ten months' run. It is a time of year, therefore, when the exhibiting photographer begins to think about the production of his prints and the selection of titles for them. If in the latter regard difficulty be felt Mr. Baldry comes along with his selection, "chosen from the literature of Great Britain and America," to save the aspirant for gallery honours all trouble in the matter. Should your photograph be a landscape you have only to refer to one of thirteen sections to find a suitable poetical name for it. Under marine, you have three series, "open sea," "coast," "shipping"; under "Figure," nine series, and the volume is rounded off with "Sport and Animal Life," "Architecture," and "Topographical." The book contains quite 3,000 titles, and must have necessitated enormous labour on the part of the compiler. Some of the quotations are so long that if they are used extensively society secretaries who have the preparation of catalogues to see to may well be excused for taking exception to them. Photographers who make the exhibition of their work a constant practice will thank Mr. Baldry for the source of reference for unhackneyed titles with which he provided them. We shall be curious to see if there is much call for the author's assistance during the next ten months; also if there are any repetitions.

Patent News.

The following applications for Patents were made between August 2nd and August 6th, 1904:—

Washing Plates and Films.—No. 16,851. "Improvements for drying and washing photographic plates and films." William Lawrence Parkinson.

Changing Device.—No. 16,877. "An adapter and magnetically controlled flat film changing device for photographic cameras." Alexander Milne.

Reproductions.—No. 17,009. "Improvements in and relating to photographic reproductions." (John Jacobson, United States.) Complete specification. Henry Harris Lake.

Reproductions.—No. 17,036. "Improvements in and relating to photographic reproductions." (John Jacobson, United States.) Complete specification. Henry Harris Lake.

Magazine Cameras.—No. 17,155. "Improvements in magazine photographic cameras." Herbert Edward Hickox.

New Process.—No. 17,192. "New and improved photographic process." Ludwig Strasser.

ERRATA.—Mr. T. Thorne Baker has drawn our attention to an error in his article on "The Composite Print in Three-Colour Photography" in our last issue. In the last paragraph but one the final sentence, "and similar to that of $\lambda = 5896$ " should read, "and passing light of from about $\lambda = 450$ to the A end of the spectrum."

New Apparatus, &c.

"Ensign" Developing Canisters. Sold by Houghtons, Limited, and 89, High Holborn, London, W.C.

Notwithstanding the number of patent developers that have been placed on the market lately, there are always a great number of people who still prefer to use a standard pyro-soda formula, for all exposures that are likely to have been under. There has been nothing to equal a good pyro-metol formula, considering the popularity of the pyro-soda and pyro-metol for

given by the Imperial Company, these developers in a cheap handy form are likely to at once meet with the recognition that undoubtedly deserve. The "Ensign" Developing Canisters contain sufficient chemicals to make up 40 ozs. of developer of standard strength; and as they are sold retail at 1s. 3d., we do not think that any amateur, however economical, will consider that they are dear. Most workers are in the habit of diluting their solutions; they are something like half the strength given in the standard formula, and both of these developers will stand a considerable amount of dilution without their valuable qualities being materially affected. They are put up in air-tight lever-top tins, and the contents should keep excellently for a considerable time.

The "Primus" Focal Plane Camera," sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

The principal feature of this camera is the style of the shutter, which instead of having an adjustable slit, as in most other focal plane shutters on the market, has a blind with five openings

different widths, either of which can be set as required. It appears to be a very simple shutter indeed, working extremely well and efficiently. Either opening can be wound up at once for use, the clamping arrangement is apparently very secure and strong, and that there appears no chance of a plate receiving an accidental exposure.

from the next opening in the blind. The finger release is conveniently placed, and a pneumatic release can be fixed if necessary. Exposures can also be given by setting the shutter to the width of the plate. As the shutter is wound up or the tension tightened, small numbers come into view on the left-hand of the camera, thus indicating exactly the aperture and speed of the plate or roll-holder is in position. The body of the camera which is really the shutter—is thoroughly well made in wood, lined with leather; the front is supported by extending spring arms, is made in mahogany, ebonised. The front is fixed by simply pulling out and replaced by pushing back. The lens board is stable for all positions. The lens supplied is the Aldis Anastigmat, working at F6, and is fitted in focussing jacket. The dark slides are of metal, and hold one plate each. They are very convenient to carry. Direct view-finder, screw and bushes for tripod, covered focussing screen, etc., are included, and the whole packs in a neat black leather case, forming an admirable little outfit for the tourist.

"Platino" Platino-matt Collodio Chloride Paper. Sold by The Leto Photo Materials Co., Ltd., 9, Rangoon Street, London, E.C. This P.O.P., which is of the popular matt collodio chloride type, features of its own that should make it much used. Prints on paper have a richness in the shadows and clearness in the highlights very suggestive of carbon. The range of tones obtainable extends from red-brown to warm black. It is necessary to print deeply until the shadows develop a distinct bronze tinge, as prints lose considerably during the toning processes. Wash in water until the last washing water is perfectly clear. The prints are then first partly toned in the following gold bath. Toning must not be carried on too far, but only until the prints seem to have changed colour. (A long immersion will yield blue-black and short immersion brown-black tones in the subsequent platinum bath.) Water, 17 ozs.; acetate of soda, 1 oz.; gold chloride, 1 gr. After toning, wash for a minute or two, and continue in the following platin bath, until the desired effect has been obtained: Water, 9 ozs.; phosphoric acid, 2 drs.; chloroplatinate of potash, $7\frac{1}{2}$ grs. Then fix in two to three changes of water. Fix for ten minutes in 10 oz., water 20 ozs., and give a final washing for at least one hour in running water or eight to ten changes. Rich sepia and red tones are obtained by diluting the above solutions with an equal quantity of water, and proceeding in the same way as for black tones.

We commend the excellent way in which the paper is packed, each couple of cut sheets being placed film to film, and each couple divided by a protecting piece of plain paper.

THE THORNTON-PICKARD 1904 PRIZE COMPETITION.

£30 in cash prizes are offered by the Thornton-Pickard Manufacturing Co., Ltd., this year in their annual prize competition. The prizes on this occasion are all of equal amount, viz., £5 each in each class. The classes are as follows:—

Class 1 (six prizes of £5 each).—For pictures taken with any of the Thornton-Pickard cameras and shutters, except "Focal Plane" and stereoscopic. Class 2 (five prizes of £5 each).—For pictures taken with the Thornton-Pickard "Focal Plane" shutter. Class 3 (six prizes of £5 each).—For pictures taken with any of the various types of the Thornton-Pickard shutters except "Focal Plane" and stereoscopic. Class 4 (three prizes of £5 each).—For stereoscopic pictures taken with the Thornton-Pickard stereoscopic shutter.

The latest date for sending in photographs is October 1. Full particulars and rules will be furnished on application to the Thornton-Pickard Manufacturing Co., Ltd., Altrincham.

CARDINAL VANNUCELLI, accompanied by the Archbishop of Westminster, and a numerous suite, paid a visit to the Italian Exhibition at Earl's Court last Wednesday afternoon. Some time was spent in the sacred art section, and the party inspected the famous model of St. Peter's at Rome, a work of art carried out by Pius the Seventh. The visit, it is understood, was made by personal desire of the Pope. Several photographic groups were secured of the party between the time of their arrival and departure.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
23.....	Southampton Camera Club	Experiments of Flashlight Work.
23.....	Nelson Photographic Society...	{ Some Printing Dodges. Mr. A. Punkett.
24.....	Everton Camera Club	{ Album and Hypo Toning. Demonstrated. Mr. J. Hawkins.
24.....	North Middlesex Photo. Soc. ...	{ Natural History Photography. Mr. G. T. Harris.
25.....	Watford Camera Club	{ Competition—"Wild Flowers in Nature."

WALSALL AMATEUR PHOTOGRAPHIC SOCIETY'S PICNIC.

On Thursday, June 30, the members of this society held their annual picnic, the district visited this year being Tewkesbury, followed by a trip up the River Avon to Evesham. At Tewkesbury some of the party paid a visit to the Abbey, others contented themselves with a look at other places of interest in the old town. At noon they started up the river per steam launch. Luncheon was partaken of on board, and soon after arrival was made at Pershore, where an hour and a half's stay was made for the purpose of seeing the Abbey and looking through the grand old town. Tea was served on board near Cropthorne Weir, and after a most enjoyable trip through charming scenery arrival was made at Evesham about seven o'clock, where a few pictures were taken of the Old Abbey Tower.

The Walsall Amateur Photographic Society is to be congratulated on its "go-ahead" spirit in catering for these enjoyable outings in the summer, of which there have already been four half-day excursions to various places, and two more to come later in the season; and also on their roll of members, numbering over a hundred and twenty, making it the strongest society (excepting Birmingham) of its kind in the Midlands—a success due, in no small measure, to the energetic and indefatigable honorary secretary, and a few of the committee who go to a great deal of trouble in arranging both their summer and winter programmes. The thoroughness with which the executive enter into the spirit of affairs is evidenced by the fact that the salient features of the picnic above recorded have been printed, accompanied with no less than seven excellent half-tone reproductions of places of interest visited, and also a group of the members taken in Abbey Grounds, Pershore. Printed on art paper and distributed among the members, it forms an interesting souvenir of the outing. Among other attractive items announced for next session is the bi-annual ball, and an engagement of the famous war correspondent, Mr. Shelley, who will give his lecture on "The Kodak in Peace and War." Full particulars and information concerning the society can be obtained on application to the hon. secretary, Mr. W. T. Comer, of 6, Arcade, Walsall.

FORTHCOMING EXHIBITIONS.

August 16-20.—Royal Cornwall Polytechnic Society Photographic Section. Secretary, Edward Kitto, The Observatory, Falmouth.

September 14-15.—Cambridge Photographic Society. Hon. Sec., T. J. Scowdon, "Sunny Side," Guest Road, Cambridge.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

October 15-29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

- October 19-22.—Rotherham Photographic Society. Hon. Sec., H. C. Hemmingway, Tooker Road, Rotherham.
- November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.
- November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.
- November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.
- November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.
- November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
- November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.
- November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
- November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.
- November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.
- November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.
- December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.
- December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.
- December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
- December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.
- December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.
- January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.
- January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Park, E.
- January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.
- February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.
- February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.
- June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills. Leeds.

FORTHCOMING COMPETITIONS.

- September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.
- October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
- October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.
- October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.
- October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Man Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £100 for lantern slides and prints made with Barnet products. E. J. Barnet and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Commercial & Legal Intelligence

KELVINDALE CHEMICAL CO., LTD.—Capital, £5,000, in £1 shares. Objects: To acquire from J. Meikle, manufacturing chemist, Ruchill, Glasgow, the whole stock, plant, book debts, and other assets of the Kelvindale Chemical Company, Limited (in liquidation) and to carry on the business of general chemical manufacturers, distillers, and dealers, etc.

FIRE at the Albion Albumenising Company's Works. —Damage estimated at £1,000 was done by fire early on Saturday morning in premises at 128, Sauchiehall Street, occupied by the Albion Albumenising Company, photographic dealers and camera makers. The establishment is situated on the second flat of a four-storey building, and, in addition to the destruction by the flames, considerable damage resulted from smoke and water.

PHOTOGRAPHY COMPANY, Limited.—Registered August 6th, by Deeds, Weld, and Dixon, 1, Lancaster Place, Strand, W.C. Capital, £20,000 in £1 shares. Objects: To carry on the business of photographing fine art dealers, publishers, lithographers, engravers, stereotypers, electrotypers, photo-lithographers, dealers in photographic apparatus and apparatus, dealers in mounts, frames, materials, chemicals, stationery, and other glass, scientific, and other instruments, and photographic stationery, etc. No initial public issue.

ANIMATED PICTURES of Armagh Cathedral.—The Irish Animated Photo Company were specially engaged for Monday last, to project in the Round Room, Rotunda, Dublin, their latest achievement in cinematographic photography in the consecration and re-opening of Armagh Cathedral; this picture takes in the procession of Cardinal Cullen, dignitaries and clergy; snapshots of the Maynooth Union of 1804; also shown, and the "Herald" go-as-you-please race to Naas; the local regattas; the King and Queen and Viceregal party at the regatta during the recent visit; Leopardstown, Ashtown, and other meetings, with numerous other subjects.

JUDGE as Art Critic.—At the Southport County Court, yesterday before His Honour Judge Shand, Annie Rymer sued Isidore Newman, 11A, London Street, agent for the British Artists Association, for return of 15s. paid by her for two enlarged photographs, on the ground that they were unsatisfactory. Plaintiff said that defendant called upon her and induced her to give an order for the enlargement of two photographs. He told her that there would be no charge for enlargements, but that the frames would cost 15s. The sum was paid before the work was done, and when the enlargements were finished she would not have them, because they were not worth looking at and she would not like to have them in the house. Mr. H. T. St. John (who defended): You say they are not good enlargements? Plaintiff: Can't you see for yourself? Why, if that young man (the subject of one of the photos) knew that he had been made to look like that, would come back from New Zealand and thump him (defendant). Honour inspected the photos and the enlargements, and remarked that while the photographs were bad the enlargements were atrocious. Judge gave judgment for plaintiff, with costs.

MESSRS. GIBSON AND SONS, of Penzance, are now exhibiting a series of photographs of the fleet at anchor in Mount's Bay. The photographs have been taken from several points of vantage, and give a fine panoramic effect.

News and Notes.

THE Blairgowrie and District Photographic Association are to have an exhibition from 6th to 11th February, 1905, entries closing January, 1905.

AUSTIN-EDWARDS Monthly Film Negative Competition.—The prize camera for current month has been awarded to Mdlle. Louise Hunt, 1, Campden House Road, Kensington, for her negative, "A Corner of a Studio."

ILFORD, Ltd., has asked us to draw attention to the fact that the £50 offered in the Ilford Photographic Competition will be paid in cash. Full particulars will be sent post free on application to Ilford, Ltd., Ilford, London, E.

A copy of the "Official" Guide to Bude has been sent us. It is an admirable example of printing, both as to letterpress and pictures. The latter, we note, are reproductions of photographs by S. Thorn, 17 and 18, Crescent, Bude.

We understand that Mr. Richard Kearton has made such an excellent recovery from the operation he recently underwent for appendicitis, that he is now hard at work writing his new nature story book, which will be published by Messrs. Cassell and Co. during the autumn.

THE nuptials were solemnised at the Wycliffe Congregational Church, Hull, last week, of Laura Constance Barry, daughter of Mr. W. Barry, photographer and artist, Park Street, and Albert Edward Davenport, eldest son of Mr. E. Davenport, Alliance Avenue, Hull.

AMONGST the pictures promised to the Newbury Photographic Exhibition next month are some from the Princess Louise of Schleswig-Holstein, who is showing some of her work taken in Ceylon. Any photographers who wish to enter pictures for this exhibition should at once apply for schedules, etc., to Mr. E. J. Forster, Guildhall Club, Newbury.

A PHOTOGRAPHIC Competition, which will be of considerable interest to amateurs, is at present running in "London Opinion." Practically no conditions are imposed. The prints may be of any kind, of any size, and the subject may be anything the competitor likes to select. The prizes are numerous. The first is £20 cash, and the second £10 cash. There are also four other prizes, consisting of various Kodaks. In addition to these, three cash prizes are offered to readers under twenty years of age.

SOUTHPORT Photographic Society.—The members of this society had an excursion on Monday to Furness Abbey, under the leadership of Messrs. J. Lambert (president) and J. M. Petrie. The Abbey was reached at 10.45, and several hours were very profitably spent in photographing the ruins of this ancient and interesting pile. Luncheon was served at the Abbey Hotel, and later the party proceeded to Carnarvon, where glimpses were obtained of the important shipbuilding yard of Messrs. Vickers, Son, and Maxim.

CHANTREY Bequest. Finding of the Commission.—The Select Committee on the Chantry Fund, which has been sitting for some time past, under the chairmanship of the Earl of Crewe, has presented its report. The committee are practically unanimous in arriving at the conclusion that the fund, as at present administered, does not fulfil the intentions of the testator, and they make various recommendations for the purpose of bringing about a change in this respect. We wonder what the ultimate result will be?

SCIENTIFIC Holidays.—About 150 members of the French Revue Générale de Science visited York recently. They are touring the British Isles, and have chartered the steamer "Ile de France," in which they sailed from Boulogne for Scarborough on Sunday. They inspected the Roman remains, the ruins of St. Mary's Abbey, and the Hospitium. The programme also included a visit to the Minster, the city walls, the Guildhall, York Castle and Clifford's Tower. The party returned on the evening of Scarborough, and proceeded to Scotland in the

"Ile de France." Thence they go to the Orkney Islands, and afterwards to North Wales and Dublin, returning to France on the 24th inst.

THE Kodak Exhibition held in the Midland Hotel Hall, Manchester, has been attracting much interest in that city. A series of 160 enlargements from negatives taken by amateurs with small cameras are ranged along the walls, and they are excellent productions. Numerous demonstrations are given daily on all phases of photography. A unique feature of the exhibition is the "Royal Room," containing enlargements of photographs of the King and Queen, and also a screen of photographs from the negatives taken by Queen Alexandra, who is an ardent devotee of the Kodak. The lantern lectures of Dr. Dixon have constituted one of the features of the exhibition, which has proved a great success.

A **NOTABLE** feature of the exhaustive report by Sir William Garstin concerning the basin of the Upper Nile are the photographic illustrations it contains. The photographs were taken by Mr. H. Samuel, M.P., Mr. G. Butcher, late of the Uganda Civil Service, and Major Loughlin, of the Uganda Rifles, and they certainly add greatly to the interest of a most informing work. Some typical pieces of scenery are given, such as the anthills in the Buddhu district, a causeway across a swamp, the Ripon Falls, and the source of the White Nile. Views of the Congo Free State and many other photographs are printed, and it is not surprising that 17s. is marked as the price of the Blue Book.

To Combat the Metre.—An association has been formed, which will be known as the "British Weights and Measures Association," having for its object the defence, standardising, and simplifying of British weights and measures. The society will take up a strongly antagonistic attitude to the enforcing of the metre as a British standard, and it proposes eventually to introduce simplified and scientifically related weights and measures based upon existing British measures. Offices have been taken at 25, Victoria Street, Westminster, and Mr. Geo. Moores, F.S.S., of Manchester, has been appointed secretary, of whom all particulars can be obtained, and who will be glad to receive the names of persons wishing to become members of the association.

THE Organising Committee of the Berlin Exhibition, Messrs. Schultz, Hencke, and Franz Goerke, have been compelled to issue a notice cancelling the exhibition, and consequently all the arrangements they have made for the representation of British work. They point out that the session of the Diet in the Deputy House (where the exhibition was to have been held) is unexpectedly called for October 18 instead of the middle of November as usual, a thing which has not happened for fifteen years. The Committee was anxious that the exhibition should be held in the excellent rooms of the Deputy House, and they point out that it is impossible, at this date, to obtain suitable accommodation in place of the rooms of which they are deprived. They regret that their work, and the great trouble taken by exhibitors abroad has been in vain, but they hope that those who have already promised their assistance will come forward again next year, when they propose to renew their efforts to organise an international photographic exhibition in Berlin.

HAND Cameras at the Bradford Exhibition.—A difficulty which probably never entered the minds of the authorities when sanctioning the promiscuous admittance into the exhibition grounds of hand cameras (writes a correspondent to the "Yorkshire Daily Observer") has recently arisen, and, indeed, has already given cause for considerable dissatisfaction. Probably the most interesting feature of an excellent exhibition, from the point of view of the average amateur photographer, is the Somali Village and its dusky inhabitants. This field closed to him, the bearer of the Kodak can have little further interest in the place as a happy hunting ground for the exposure of films—with the possible exception of an occasional snapshot at the water chute at a critical juncture of the boat's career. Unfortunately, however, the Somalis themselves have put a barrier in his way by the sudden development of an antipathy to being "taken" as intense as it is inexplicable to the unsophisticated. The appearance of a camera anywhere within range appears to act upon the Somali temper

in the same manner as the proverbial red rag is said to act upon a bull, and woe betide the hapless enthusiast whose apparatus comes within measurable distance of the villainous-looking spear-head borne by the valiant Somali warrior. As to what would be the consequence of the camera being put out of action, or a resort to personal violence on the part of the owner, one can only conjecture, but it is pretty safe to assume that the eternal craving for "backsheesh" provides the native with his motive, he, of course, having an interest, more or less direct, in the sale of the official portraits. Perhaps the committee may see its way to at least effect a sort of compromise.

THE R.P.S. Exhibition.—The Secretary of the Royal Photographic Society has asked us to draw the attention of our readers who are thinking of sending their photographic work to the New Gallery this year that entry forms and photographs must reach the Gallery, 121, Regent Street, London, W., by September 8, or September 9 if delivered by hand. The Exhibition will be divided into five sections, as follows: 1, Pictorial photographs, invitation collection; 2, pictorial photographs, competitive section; 3, scientific and technical photography and its application to processes of reproduction; 4, general professional photographs; 5, photographic apparatus and material. Intending exhibitors in the Competitive Section should note the new rule, which states that "no exhibitor will be allowed to submit for selection more than six photographs and six lantern slides." No charges, however, are being made this year for wall space in this section. The Exhibition will be inaugurated on Wednesday, September 21; by a private view, followed in the evening by a conversation, and will remain open daily (Sundays excepted) from Thursday, September 22, until Saturday, October 29, 1904, from 10 a.m. to 6 p.m. It will also be open on Monday, Thursday, and Saturday evenings, from 7 to 10 p.m., when lantern slide exhibitions will be given in the North Gallery. Admission, during the day or evening, one shilling. Members of the Society have free admission to the Exhibition upon production of their cards of membership. They receive a book of six passes (for presentation), and can purchase tickets or books of passes at half price. Every exhibitor who is not a member is entitled to a non-transferable season ticket. Members of affiliated societies can obtain tickets of their respective secretaries at half price. Entry forms and full particulars can be obtained on application to the Secretary, Mr. A. W. W. Bartlett, 66, Russell Square, London, W.C.

A SERIES of remarkable moving pictures has been recently secured at the plant of a prominent Pittsburg machine company by the American Mutoscope and Biograph Company with the aid of the Cooper Hewitt light. These pictures, states the "Scientific American," were taken for exhibition in St. Louis in the private auditorium of the company on the Fair grounds. When "moving pictures" of the Jeffries-Sharkey heavy-weight contest at Corey Island were taken the scene was an arena interior. The ring was cut down to 20ft., and 400 arc lamps were strung above it, the heat from which caused the combatants much discomfort. In several of the pictures in question the entire length of a quarter mile aisle is shown, and at no time were more than sixty-four of the mercury vapour tubes used. The camera was placed on a platform fifteen feet from the ground, suspended from an electric travelling crane. The crane was moved slowly down the long aisle about 50 feet in the rear of the Cooper Hewitt lamps, the latter being also suspended from a travelling crane moving at equal speed. So far as possible in the taking of these pictures, any sunlight through the glass skylights of shops was taken advantage of, but it is not safe to depend very much upon the help of the sun in a moving picture which is four or five minutes in the taking. The sixty-four lamp tubes were hung in sets of eight, in eight frames. They required only 30 to 40 kilowatts, or about one-fifth of the energy consumed by the four hundred arc lamps referred to above. The camera made fifteen exposures a second, or nine hundred to the minute. Among the more interesting pictures are the welding of a ten-foot ring for an electric generator, the railway motor aisle, the forging of a ten-ton steel crank shaft by a thirty-ton steam hammer, one of the eight main quarter-mile aisles devoted to the construction of big power types and a six minute view of employees leaving one of the shops in East Pittsburg.

METEOR Photography.—In recent years the "Perseids" have afforded the most prolific annual display, for since the desertion of our planet of the "Leonid" (November) shower they occupy premier position among our annual fêtes of shooting stars, with "F. R. A. S." in the "Daily Chronicle." Amateur photographers have, in these periodic displays, fine opportunities of "getting something" out of the ordinary, the credit whereof would resound in many places. Eye observations are, at the best, rather uncertain; one never knows where or when the thing is going to appear, and is therefore unprepared to note the various characteristics and to repeat the nursery rhyme. But the extra-rapid sensitised plate does not get excited or surprised; it remains calm and collected, and records everything bright enough for it to "see" just as it sees it. To attempt meteor-photography one should take an ordinary camera—the greater the effective aperture of the lens the better—focus it for "infinity," after having loaded up with a very rapid plate, of course, and expose on the directly overhead or on some well-known constellation, such as "Swan" (Cygnus) or "The Lyre." It is no use trying to snap meteors, for as "sitters" they are incorrigibly erratic. Just of the slide and let the exposure "rip" for, say, thirty minutes, then expose another, and meanwhile develop the first. The brighter stars owing to the rotations of the earth on its axis, will have imprinted "trails" on the plate, all symmetrically arranged as arcs of circles around the pole star as centre. Should a meteor trail have been "captured" it will be easy to recognise, for the chances are thousands to one against its being parallel to the star trails. It will be inclined to them, and therefore at once recognisable. If the observer wavered the sky whilst exposing his plates and notes the times and positions at which the brighter "shooters" appear, it will probably be found possible subsequently to determine the correct time at which the object recorded on the plate shot across the sky, and the lucky photographer will have achieved a fortunate and valuable astronomical success.

MULEY Mentality.—Mohammed was twenty-five years of age when he married Kadijah, who was fifteen years older, and who more than anyone else strengthened the hand of the Prophet in his labours to combat idolatry and establish a new and purer creed among the people of his race. The blood of the Prophet drags languidly through the amiable arteries of Muley Abdul Aziz, Emperor of Morocco, written Mr. Poultney Bigelow in the "Morning Post," and it has been dragging languidly for the past twenty-five years. Muley is in advance of his people; he is very much "up-to-date." Mahomed of Mecca could neither read nor write and knew little of the world save what he learned from driving a camel over the Arabian desert. But Mohammed like Paul Kruger, knew his own people, and for a politician that knowledge is more precious than all the volumes in the British Museum. Muley might do worse than invite the Hon. Richard Croker of New York and Vantage, to Fez for the unique purpose of teaching him how to behave in times like these. Mahomed disapproved portraits because to him they suggested idolatry. To-day no orthodox Moor permits himself to be photographed, no orthodox Moorish house contains pictures of people. Muley, however, ordered a Kodak—one, but a dozen. He created the post of Court Photographer, and had his sacred Moslem person photographed; and if there could be anything worse than that, it was to have this same photograph multiplied and sold at one cent apiece throughout the cities of the Mediterranean to the scandal of every Moslem from the Himalayas to the Pillars of Hercules, and the corresponding delight of Jews and Gentiles. It was a Christian who put this idea into the aimable head of Muley. For he said to the successor of Mohammed: "Your Majesty is a great Monarch—like your brother of Great Britain. King Edward is photographed; indeed many members of his family take photographs themselves. If your Majesty proposes to be a real ruler like King Edward, then you too must have a Kodak!" And so to-day there are in Fez dozens of photographic boxes of every imaginable make, one, for Imperial use, being of gold, and having cost more money than Mohammed himself ever spent on his fifteen wives in an one year as Chief Prophet. As near as I can get the figures to-day Muley has spent several thousand pounds on this one gold instrument and its accessories.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

THE FIASCO AT ST. LOUIS.

To the Editors.

Gentlemen,—Indirectly I hear that the BRITISH JOURNAL OF PHOTOGRAPHY has been kind enough to reprint the "Fiasco at St. Louis," which appeared in the issue of July 16 of the "Photographer" (New York). The article in question is absolutely misleading. I replied to it. The fiasco is solely 'due' to the outrageous management of the Exhibition authorities, to the cries of the mob of non-pressers, all of whom wished to have a voice in the show. The dignity of the British photographers and the British Government is a positive relief to all self-respecting photographers. Not my followers did not participate, but all other self-respecting photographers. Why? Because I dictated. —Bosh!—Yours truly,
ALFRED STIEGLITZ.

Mel Igleshof, Igls, Austria, August 9, 1904.

We shall be happy to reprint Mr. Stieglitz's reply when it arrives.—Eds. "B.J.P."]

THE "NEW" STEADMAN SYSTEM OF EXPOSURE AND PLATE SPEED MARKINGS.

To the Editors.

Gentlemen,—The interesting point about Mr. Steadman's communication in the BRITISH JOURNAL OF PHOTOGRAPHY of August 5 is the one in which the methods invented and published by other inventors (and largely used by the public) are paraded by Mr. Steadman as "my system of exposure." Where is one original point in his plan he expounds?

Is the plan of taking a "numerical statement of the light's intensity" by measuring with actinometer the light actually falling on the subject? I was the one who introduced this as an essential part of the finite exposure system.

Is the plan of using a diaphragm of such size for a certain plate that the actinometer and exposure time shall be the same? I was the first to invent this method, and it is largely used.

Is the plan of taking the first darkening of the sensitive paper as a guide instead of darkening to a stated tint? I was the first to do this method, and it is largely used.

Is the plan of combining the above three methods and publishing a table of diaphragm values to use with different speeds of plates to make the exposure the same as the "first darkening" actinometer test? I was the first to give such a table, which is to be found in the instructions of all my meters in the "Watkins Manual" in "Exposure Notes."

Is the plan of giving on a box of plates as their speed that size of diaphragm which makes exposure and actinometer time equal? Wynne has adopted this for a long time.

Is the plan of using an ordinary print out of chloride of silver for the actinometer? The first devisers of actinometers always adopted this, until Sir William Abney pointed out in a BRITISH JOURNAL Almanac about 1886 that a *sine qua non* in an actinometer is to use the same haloid of silver for testing the light as is used in the sensitive plate. Is it the plan of selecting some particular brand of paper, and therefore getting a new standard for the time of first darkening? Then we shall have a plentiful crop of Luma and Stella

Velox and Mariona plans, paraded (not by the makers of these excellent papers) as "my system of exposure." The table of subject values given by Mr. Steadman is in my experience far too complex. I commenced fourteen years ago by giving a much shorter table of subject variations for use with an actinometer plan. But I have even then this unnecessary for the average worker, and it is most convenient to give one standard subject value only, which applies in all cases out of ten, whether for outdoor, indoor, or portrait. For

the tenth exceptional case of sea view, glacier, or all-white subject the necessary variation from the standard can easily be remembered by the photographer.

I am not writing to criticise details of Mr. Steadman's plans. But I should point out that the average eye is incapable of timing the darkening of an actinometer (whether "first darkening" or to a tint) under $1\frac{1}{2}$ or 2 seconds. As far as I can judge by a rough trial, P.O.P. or Solio shows "first darkening" in brilliant summer sunshine in one-third of a second, which is a time quite impracticable for observation. If a paper slow enough for its "first darkening" to be used as an outdoor test is used as an actinometer, then it will be quite useless for indoor work, as it will take far too long to show any light effect. To use the same paper for indoor and outdoor work the first darkening plan must be used in the former case and a much darker tint or painted standard out of doors.—Yours truly,

Hereford, August 11.

ALFRED WATKINS.

DEVELOPERS WITH ACETONE.

To the Editors.

Gentlemen,—Mr. Thorne Baker's answer to my previous letter is not flattering to the average reader of the B.J., whom he obviously classes in that large category so well described by the Chelsea sage as "mostly fools."

What your contributor has done has been merely to prove that a shorter time of development gives a less steep gradation—a fact which, I must confess, I thought was known to every photographer to be he one of the Carlylean majority or minority.

Surely, considering the somewhat close acquaintance which Mr. Baker evinces, possibly undesignedly, with German writers, his statement that "definite historical notes are difficult to obtain on the subject" is a little inexplicable. He has merely to refer to various volumes of Eder's "Jahrbuch" or even the same author's "Handbuch der Photographie," Band III., p. 485, to find authoritative historical notes on the use of acetone.—Yours faithfully,

LEONARD SMITH.

Norwood Junction.

A DISCLAIMER.

To the Editors.

Gentlemen,—Permit us to call your attention to the fact that your notice re the prosecution of a shopkeeper in Wardour Street in your issue of July 22 is calculated to be harmful to others who are engaged in the sale of postcards in this locality, and you do not give name and address, and it is left to the public to surmise where the fault was committed.

As there are such a limited number of retailers of postcards in Wardour Street, we think that in fairness to those who conduct their business in this class of goods in such a manner as to eliminate any prints of a questionable nature, you should make it clear where the stigma rests.—Yours faithfully,

NILSSON AND CO.

16 and 18, Wardour Street, London, W., August 10, 1904.

[At this distance of time we cannot recall the name of the delinquent, but we have pleasure in stating that it was not that of Messrs. Nilsson and Co.—Eds. "B.J.P."]

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

Answers to Correspondents.

- *** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- A. M. Cromack, 30, Newborough, Scarborough. Three Photographs of Groups of Piers.
- A. Phillip, George Place, Stewart Avenue, Bo'ness, Linlithgowshire. Photograph of Town Hall and Carnegie Library of Bo'ness.
- A. Osborne, 2, Chelsea Villas, Dudley Road, Clacton-on-Sea. Photograph of Wesleyan Officials.

ADDRESS WANTED.—VERT and Co. ask: "Will you kindly let us know the address of Messrs. Underwood and Underwood, publishers of stereoscopic slides, etc.?" In reply: Messrs. Underwood's address is Haddon Street, Regent Street, W., and New York.

COPYRIGHT IN AMERICA.—R. GALLAGHER says: "I wish to copyright some views in America. Information as to how I am to proceed and cost of same will oblige." In reply: America is not a party to the Berne Convention, therefore you will not be able to make your pictures copyright in the States.

BOOK WANTED.—W. H. TURNER asks: "Is it possible to get a book on posing in studio? If so, kindly furnish me with the name and address of firm from whom it can be obtained." In reply: Yes; "The Studio and What to Do in It," by H. P. Robinson. Photographs," by Robert Johnson, will give you some useful information.

CELLULOID VARNISH.—W. B. AVERY writes: "I have a lot of waste film negatives, and wish to make them into celluloid varnish. How do I proceed?" In reply: The best plan is to boil the film negatives until every trace of gelatine has been removed and the celluloid is quite clean. Then, after it is well dried, cut into small pieces and dissolve in amyl acetate in the proportion of 80 grains in 20 oz.

BOOK WANTED.—ARS says: "I shall be glad if you can inform me of a really good book on how to work up enlargements, one that thoroughly goes into the art in every way." In reply: There is no work entirely devoted to finishing enlargements. The "Art of Retouching Negatives and Finishing and Colouring Photographs," by Robt. Johnson, will give you some useful information.

INJURED GLASS POSITIVE.—A. WALLHAUSER writes: "With regard to photograph enclosed, could you inform me where I could get the face filled in, as it has accidentally got rubbed off, or is there any possible way of reproducing it? The photo is greatly valued, and any information you can give as to it being restored will be greatly esteemed." In reply: Nothing can be done with the picture, as nearly half the face, and film, have been removed; also the hands have been rubbed off.

GUM FOR STAMP PHOTOS.—L. P. WISNER writes: "Will you please give me a formula for making gum that can be applied to the backs of home-made stamp photographs?" In reply: Dissolve $\frac{1}{2}$ lb. of the best gum arabic in a pint and a half of cold water. When quite dissolved, add two teaspoonfuls of glycerine, and 1 oz. of honey. Strain the mixture through flannel. The glycerine prevents the gummed paper from cracking and curling

up when dry. Ten drops of oil of cloves added to the mix will keep it good for a long time.

COLOURED MATT VARNISH.—CYMBIC asks for a formula for a coloured matt varnish to be applied cold to the back of negatives requiring "helping" in the shadows. In reply: Make up following matt varnish—Gum sandarac, $\frac{1}{2}$ oz.; gum mastic, 48 grains; ether, 5 ozs.; benzole, $\frac{1}{2}$ oz. Allow to stand several days before adding the benzole, then stand for days and filter, and add sufficient alcoholic saturated solution of iodine—usually about 1 part to 24 of matt varnish. Colour can be removed in patches if necessary by applying little saturated solution of hypo.

STUDIO QUERIES.—J. P. and S. say: "We shall be obliged if you will kindly inform us which would be the best way of light for a studio. We are building a new studio, and wish to have both ends if possible. We enclose two plans, which have been suggested, but would not the plan marked No. 1, with the windows cause shadows on the floor where the sitters sit? The plans are drawn to the scale of $\frac{1}{2}$ in. to the foot." In reply: We should prefer the design of No. 2, but with glass in the middle of the studio (if both ends are to be used), having about 5 ft. 6 in. at each end opaque. But the aspect of the building is not stated, we cannot advise further.

SHOW CASES.—BAILLEBORE Studio Co. ask: "(1) Where can I show cases for outside display, and what colour, design, etc., suits the best? I generally use dark grey mounts. Where can I get a block (line process) with an attractive design for advertising photography in a local paper. I supplied it with a half-tone block but they could not use it as they printed with 'Linotype,' but they can use any other kind; what of design do you consider the best?" In reply: (1) Messrs. Sage and Co., Gray's Inn Lane, and Messrs. Drew and Cadell, Holborn, are makers of show cases. But we should think could get them made for you in Ireland. A maroon will be a suitable colour. (2) No doubt the newspaper people who would like to use the block will obtain for you one that will suit their printing. The design is, of course, a matter of taste, and you can design for yourself.

LENS TROUBLES.—J. S. (Ceylon) writes: "I have been much disappointed with the results obtained on using two new lenses recently purchased, from which I expected great results—being a 12 x 10 lens, the other a 12 x 10, Series V. In use either of these lenses for outdoor groups, when one has to photograph against the light, so frequently the case here, only shade being a strip of shadow near some building, the camera out in the open, more or less facing the sun, result is invariably a hazy negative, every precaution being taken to shade the lens from the sun. On comparing the new lens recently with a rapid rectilinear (a very ordinary lens, poor covering power), the difference in brilliancy was not marked, the image as seen on the ground glass when using the R.R. lens being perceptibly brighter. Two negatives taken of the same subject under identical conditions with the two lenses show a marked difference in favour of the R.R. lens. In taking groups when any of the figures appear against the sky line, they are nearly obliterated by halation, the R.R. lens giving bright figures. The only occasions when I can get satisfactory results outdoors with either of the new lenses is when photographing with the light directly on the subject and behind the camera. For studio work, copying, enlarging, etc., nothing can be better, but I find it very risky to rely on them for outdoor work. I have an idea that both makes of lenses are deficient in projecting hoods to cut off reflected light." In reply: Both the lenses named are excellent, but they both include a much wider angle of view than do those of the R.R. form. Hence greater care is necessary to avoid extraneous light entering them when working under the conditions alluded to. We should recommend you to use a hood or box fitted on the front of the camera, so that light falls on the lenses, except from such of the subject as is required in the picture.

EX CATHEDRA.

Photography and the Detection of Forgeries. The Berlin correspondent of the "Standard," writing one day last week, says that "excellent results have been obtained by the police at Ulm by the use of photography for the detection of erasures or corrections in documents and letters in cases where microscopic examination has not been successful. Railway tickets where the stamped date could no longer be deciphered were dusted with the finest graphite and photographed, whereupon the date was easily recognisable." We had an idea that this method of detecting erasures and alterations by photography was pretty old now. It will be remembered that the aid of photography has been invoked in the detection of forgeries, and in the alteration of documents by erasure and substitution has frequently come before the Law Courts in England, and, we believe, also in France and America. But, according to this writer the thing is new in Germany, though we doubt very much if there is anything novel in it even there. Still, we know that correspondents of the daily papers must write about something, and some allowance must be made for this being the "silly season" when "big gooseberries" are being grown and "sea serpents" are swimming about.

* * *

Weather Vaticination. In view of our recent remarks on the possibility of the Meteorological Office giving us forecasts of greater accuracy and for a longer period in advance, it is worthy of note that outside efforts are already being made in a similar direction to utilise the important advantages offered by the system of wireless telegraphy. It is an old joke that the weather has been the worse since we got telegrams from America regarding it; but, as a matter of fact, a great deal of our bad weather does come from the direction of the New World, as "dirty weather" is always passing across the Atlantic, and mainly from West to East, or perhaps it would be more strictly correct to say S.W. to N.E. These storm areas influence our weather considerably, and in the summer months, though it could not be properly said that they are the cause of strong gales, yet the rains and unsettled weather we experience are directly attributable to them in the main. And in winter time when severe gales so often sweep our coasts the Marconigraphs will probably be of value in giving much longer notice of the approach of storms, and the longer notice the more the system is improved. The Meteorological Office some little time ago were in treaty with Lloyd's upon this question, but up to the present no terms have been arrived at. It is to the "Daily Telegraph" that we are indebted for the storm forecasts we refer to.

B

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued in two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all the more over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

**** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that this year the entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st, next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

Self-Lighting Burners.

Where electrical lighting with its concomitant advantage of not requiring the use of matches is not installed, the old system of first needing a match to be struck before lighting-up has been almost a necessity. It is true that self-lighting burners both with an ordinary fish-tail and with some types of incandescent burner are made; but, as all users of them are aware, the bye-pass is liable to get choked up after a time and so render the self-lighting action to become inert; hence any system not liable to this objection will be welcomed. A step in this direction has been taken by a well-known firm of chemical apparatus manufacturers, who have devised self-lighting burners, in which the employment of platinum black supplies the required means. This firm has introduced a self-lighting Bunsen burner, utilising the peculiar property of this form of platinum, and which, at any rate, in the laboratory, should be especially useful; a priori, there seems to be no reason why the incandescing of spongy platinum by the impinging upon it of hydrogen should not have a general application for illuminating gas burners if properly applied.

* * *

Acetylene Gas Illumination.

While discussing the question of gas illumination, we may call attention to a letter in a recent number of the "English Mechanic," which appears to dispose effectually of what is undoubtedly a popular idea that acetylene gas, so invaluable a light in photography, inevitably chokes up the burners in a short time. The writer says: "'M.' says that 'all burners require replacement from time to time . . . say, three months.' The Langley Station (G.W.R.) is lighted with the dry generation process of acetylene gas, and the burners have been in constant use for over three months, and all are in as good order as when first put up. In a table 'M.' gives as follows:—

	Candle Units.
Incandescent (high pressure)	30.35
" (Kern)	20.25
Acetylene gas by the dry process	31.7

If 'E. G. L. B.' wants a really first-rate acetylene gas generator let me recommend him the dry generation process. It is best for safety, simplicity, economy, efficiency, purity, cleanliness. No water, no mess, or sludge." If the process be all that the writer ("Edward Barnes, late Capt. 27th Inniskillings") claims, it is the one of all others likely to be of value for studio illumination.

* * *

Photographing the Unseen.

One of the qualities of photography, which though of the utmost value is least dwelt upon in a general way by popular writers, except in concrete cases, is the power it possesses of bringing to us a knowledge of things unseen. The most familiar instance, perhaps, is the representation of those rays of the spectrum that are utterly invisible to the eye and of whose very existence we should be ignorant were it not for the sensitive plate. In another direction we have pictures of the various positions of the limbs assumed by a horse when galloping, and which have so struck the fancy of some artists that they have reproduced them pictorially in representing a galloping horse, though no one had ever been cognisant of such positions till the camera had been brought into requisition. Present-day students have no idea of the excitement caused by the publication of the first photographs of this kind by Muybridge, of California. He was fêted and lionised, the guest of royalty, and of the most famous artists of the time; yet the only value of his pictures was the anatomical one. They were as improper a representation of what the eye saw as was the view of the

carriage wheels in rapid motion—every spoke as plain as if the vehicle were at rest. Nearly everyone has seen the views of a bullet in its flight after leaving the rifle. No one ever saw the air-waves. Then we have photographs of falling drops of water, and a great variety of cograte subjects, the most recent one published being on the effect of sound upon jets of water, an investigation which could not have been made at all without photographic aid. In a recent number of "Nature," a review of the paper is given illustrated with a singularly interesting photograph.

* * *

The British Association at Cambridge.

Much valuable work of interest to photographers has been accomplished during the visit of the British Association. Sir William Ramsay's paper on Radium, Professor Larmor's lecture on the "Relation of Röntgen Rays to Ordinary Light," Professor Rubens' communication bearing on the "Optical Properties of Metals," and Professor J. J. Thomson's discourse on "Radio Activity" are all of the highest importance. Addition to these Professor R. W. Wood, of Baltimore, described some recent improvements in the diffraction process of colour photography. The method he had invented, he said, depended on the use of three diffraction gratings placed in front of a lens. The three gratings were ruled with different degrees of fineness so as to appear red, green, and blue in colour. They possessed respectively 2,000, 2,400, and 2,750 lines to the inch, and were ruled so that overlapping squares on a single glass plate. The early gratings were faulty, but recently improvements had been made in the process of ruling. Professor Wood described the relation of his process to the Joly process, and showed how a specially ruled grating could be employed in the latter method. The difficulty of ruling such a grating was very great, but had finally been successfully overcome. In the geographical section Mr. Douglas Freshfield gave an interesting discourse entitled "Mountains and Mankind," in which he urged mountain explorers to attempt in more distant lands what the late Messrs. Adams-Reilly and Nichols, Mr. Tuckett, and Lieutenant Payer (of Arctic fame) did forty years ago with so much success in the Alps, and what the Swiss Alpine Club has done lately—take a district, and, working from the trigonometrically fixed points of a survey, fill it in by photographing with the help of the instruments for photographic and telephotographic surveying.

* * *

The Silly Season.

The time comes in every man's life when he loses faith in many of the cherished traditions of childhood, and pitches them overboard like so much useless top-hammer. Time was when we ourselves believed most implicitly in the big gooseberry. Its appearance used to be recorded without fail in our newspapers every year, and every year that gigantic berry grew more abnormal. It is perhaps as well that it should have passed away, for had it lived until now it would have increased in stature to such a degree that no newspaper—not even that of the largest circulation—would suffice to wrap it up. Now that Parliament is prorogued and the silly season is upon us, we miss our gooseberry terribly, so do the newspapers, and, if we may judge from the contents of some of them, they are hard put to it to find matter to supply its place. Fancy the "Daily Telegraph" (for example) devoting a column to "General" Booth's tour, and heading it "A Converted Sweep"! We have read the article—its title was all sufficient—because we do not appreciate tracts. This may possibly be due to our innate callousness, or perhaps because in early years we were so placed that we were surfeited with these ger-

erature. We have in our time shed tears of anguish "the converted burglar," "the converted pickpocket," "converted drunkard," and converted criminals of all and sizes. But why a converted sweep? Is not the work of a sweep as honourable an one in its way as any other reputable manner of earning a subsistence, and not a slur on a respected profession to hint that its members, like criminals, should be converted? Certainly, they get rather black, but even a nameless gentleman is as black as he is painted, and a decent sweep always dresses for Sunday. We must enter a protest against this sweeping condemnation by inference of the sweep profession, and we do so energetically, because we feel convinced that the sweeps will not long stand alone in general Booth's pillory. The photographers will come

For years thoughtless and irresponsible writers have added to them as practitioners of "the black art," and those who do not understand what a revolution has taken place in the methods of photography may imagine that the humble knight of the camera still merits the appellation "The converted photographer" looms large in the history of our imagination, but before the dream becomes a reality, we wish to put on record with no uncertain voice a protest against the ignorant assumption that photographers, as a body, are in need of public whitewashing.

Photography Fiction. Those who are familiar with the "Note Books" of Nathaniel Hawthorne will remember that he has dotted down a number of detached stories which he considered might be worked up into plots. Other writers have made the same useful foranda, very often it may be supposed, for after-ration by themselves. Mr. Bailey Aldrich, in his "Unkapog Papers," suggests several ingenious plots, which are amusingly treated in a recent number of the "Monthly Review." One of them is of photographic interest, and is thus sketched out. "In his memoirs, Potkin states the singular fact that the natives of the Malayan Archipelago have an idea that something is reflected from them when their likenesses are taken by photography. Here is the motive for a fantastic short story, in which the hero—an author in vogue or a popular actor—might be depicted as having all his good qualities actually photographed out of him. This could well be the result of a too prolonged indulgence in the efforts to look natural." First, the man loses his charming simplicity; then he begins to pose in intellectual attitudes, with finger on brow; then he becomes morbidly conscious, and finally ends in an asylum for incurable artists." This is certainly a very pleasant piece of fiction, but one is apt to smile at the idea that antipathy to portraiture is confined to the camera, and to the inhabitants of the Malayan Archipelago. It is a deeply-rooted prejudice which is prevalent over a large part of the world's face, and no doubt many of our readers have had to contend with it at places as comparatively near to this country as Algiers and Tunis. It is closely allied with the superstition of "the evil eye." Setting these considerations aside, Mr. Aldrich's idea is a fanciful one, which, in the hands of a gifted writer, would crystallise into something good. But might not the plot be twisted round a little so as to make the photographer the hero of the story? Let his work have such an effect upon him that every time he uses his camera something is taken out of him—part of his personality goes. He might at the beginning of the story be an accomplished worker, a good band and father, and one who always brought his pictures up to focus. Then he would gradually decline, under the influence of some new school he would smash focussing screw, purchase many yards of "bolting cloth," and try all he knew to make them as unlike

photographs as they could possibly be. Then he would sink lower and lower, producing pot-hunting fuzzy-wuzzies without number, sending them round in batches to the provincial exhibitions, until at last he sank a hopeless wreck of his former self—an addled egg sheltering under a pictorial wing. It seems a pity that the camera was not in evidence in Shakespeare's day, for he might have made his "Seven Ages of Man," into seven ages of the photographer. Here is another idea for the aspiring writer.

Thibet.

We may be quite sure that the expedition which has so recently reached Lhasa, the sacred city of Thibet, has several cameras in the possession of those who know how to use them, for military officers are often keen photographers, and know very well that their work often brings them within range for their lenses, as well as for their more formidable weapons, of things worth aiming at. So we may look forward some day in the near future to seeing Lhasa through the medium of trustworthy photographs. Very few travellers have, before the present time, been permitted to approach the city, which has been jealously guarded from the eye of the infidel, and we have plenty of evidence that the Lamas did their best to stem the advance of their visitors of to-day. But there have been a few exceptions to the rule. The new edition of a book has just been published, the author of which is Sarat Chandra Das, who obtained leave to visit the city more than twenty years ago, and was for six months the guest of one of the principal officials there. The reports made by him to the Indian Government were at first regarded as confidential documents, but were ultimately published in book form. There are several illustrations to the volume, the views of the city being of a diagrammatic character, while many of the pictures representing native customs are actual photographs. But it must be confessed that they are disappointing, in giving the idea that the men are posed for the occasion. Some of the customs are, to say the least, peculiar. Thus we read of a Thibetan funeral that "In every cemetery there is a large slab of stone, on which the corpse, stripped of its coverings, is placed face downwards. The officiating Lama then crosses it with lines, and while he repeats prayers, cuts it into pieces. The first pieces are flung towards the biggest and oldest vulture of the flock, called "Tankar," and the remainder to the rest. They are so tame that they come up, one by one, at the call of the priest. Last of all, the head of the corpse is crushed, and the bones pounded together are mixed with the brain, and distributed among the vultures." This is terribly gruesome and repulsive, but the photograph of the scene is tame in the extreme. There is the slab of stone, with the corpse, or a make-belief corpse, lying upon it, and the priest stands ready, with a long knife. A group of mourners, who do not mourn, stand around; but the vultures are not to be seen at all. The other photographs have the same sort of artificiality clinging to them. We must make allowance for the circumstance that when this traveller visited Thibet gelatine plates were in their infancy, and that probably he had all the drawbacks of the wet process to contend against. There was no such thing as snapshotting the natives, or the vultures, or anything else. But it is very different to-day, and possibly our expedition may bring home with it not only photographs illustrative of the manners and customs of the Thibetans, but also pictures of some of the skirmishes which have marked its progress towards the city of Lhasa.

RAYMENT'S Universal Lens Flange.—In our review of this useful addendum to the optical outfit of the photographer, published in the JOURNAL of August 5, we omitted to mention that it is obtainable of Mr. Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.

THE SIMPLICITY OF THE CARBON PROCESS FOR PORTRAITURE.

At the present time there seems to be a taste for photographs in almost every colour except the old orthodox photographic colour, and, of course, enterprising portraitists cater for it, and often by troublesome methods, such as by toning bromides, for example. But, after all, this is a clumsy way when a simpler is at hand. Those who have undertaken to produce, say, a dozen prints by this means—all of the same tone—are fully aware of the difficulty they will meet with. Now, with the carbon process there is no such difficulty, because tissues of almost every colour of the rainbow are now on the market, and whichever one is selected all prints made upon it will be of exactly the same tint. It is thought by many that the carbon process by the double transfer method, by which the pictures are non-reversed, as regards right and left, is troublesome to work. But why work the double transfer method at all? Why not produce reversed negatives? Then the single transfer method, the simplest of all photographic processes, may be used. There are many ways by which reversed negatives may be made. One is by stripping the film from the glass and printing from the reverse side. This method is troublesome, and will not, we think, appeal to the general body of portraitists. The portrait may be taken with the aid of a prism, either before or behind the lens; but a prism of good quality, suitable for a good-sized portrait lens, is a somewhat costly affair. But reversing mirrors are by no means so, as they may be had at quite a moderate cost, and when kept in a good state of polish add very little indeed to the exposure.

There is yet another method, which entails no outlay whatever. It is simply to put the plate in the slide with the glass side toward the lens, of course, making allowance for the thickness of the glass in the focussing. As the glass now used for dry plates is so uniform in thickness there need be no difficulty from this source. There is no more difficulty in developing a plate exposed through the back than when it is exposed on the film side, but the appearance of the image must be watched for from the glass side, and not from the film side, density being, necessarily, judged in the ordinary way. It may, en passant, be mentioned that negatives made in this way are free from halation arising from reflection from the back of the glass. It goes without saying that the back of the plate must be carefully cleaned before it is put into the slide. Once our reversed negative is obtained—by whatever means—the production of carbon prints from it in any colour becomes the simplest of all photographic processes. All one has to do is to expose the tissue—which may be of any colour—mount it on single transfer paper, and simply develop with warm water, and fix it in a solution of alum, and then we have a picture of unquestionable permanence. There is one thing that may be mentioned in connection with the single transfer method, and its advantage over the double, which is that the prints may be made on the coarsest surfaced papers, which is not possible by double transfer. An objection may be made to the fact that reversed negatives cannot be used for ordinary printing unless we are content to have the image, as regards right and left, reversed. But why not, at the time of sitting, if ordinary prints are thought to be necessary, take two negatives—the one reversed and the other the right way about? All modern studio cameras are fitted with repeating backs and double dark slides, and what is easier than to put in one plate one way and the other the reverse?

AN OFTEN UNSUSPECTED CAUSE OF TROUBLE

PHOTOGRAPHERS, even experienced ones, sometimes with results that they are quite unable to account for. The abstract of the paper that we gave last week, Dr. W. J. Russell, F.R.S., recently read before the Society, will possibly throw a light upon some of them. Dr. Russell, it is well known, has for a long time been devoting a great deal of attention to the effect produced on gelatine plates by the emanations from different substances. His last paper is devoted to the action of different woods, and this is of special interest to all photographers, inasmuch as their cameras and dark slides are made of that material. It was pretty well known before the introduction of gelatine plates that dry plates of the then days, of the more sensitive kind, deteriorated when they were stored for long in deal boxes, and they did not do so—at least, to the same extent—as they were kept in mahogany ones. It is, or was, not a common thing for gelatine plates that have been kept in the dark slides for only a few days to, when developed, show a marked difference in density at that portion which was opposite the fabric forming the hinges.

A few days ago we were shown by a professional photographer who had been commissioned to reproduce a number of paintings in the North—of the 12 x 10 size—some negatives with this defect. The work was finished on the Friday night, and the last six plates exposed were left in the slides; the others had been replaced in boxes. The development was not commenced till the following Monday, and those plates that had been kept in the slides were marked with the hinges fabric, as were by the panels of the shutters, and, as a consequence, the journey of several hundred miles had to be made to rectify these six negatives. Those repacked in the boxes were perfect. Another case was this. A well-known camera maker had some few years before supplied an experimenter with a 15 x 12 camera, which had been used for outdoor work for a long time, giving every satisfaction. One day, however, one of the slides, containing a couple of plates exposed on a subject—a group—was left standing in the sun for a short time, and when the plate was developed the negative showed distinct marks of the panelling of the shutter, which, by the way, was of quite exceptional thinness. The slides were sent back to the maker, who doubted the fact. Some plates were procured by him, and put into the slides, which were then stood for a time in the light. When developed, there, sure enough, were marks of the panelling, but it was clear that, by reason of the thickness of the wood (Spanish mahogany), light could have passed through. Now the recent searches of Dr. Russell would seem to throw considerable light on the subject. Dr. Russell points out in his paper that the action of the wood is greatly increased after it has been exposed to a strong light. Most workers, when they are working out of doors, take the precaution to cover up the camera with the focussing cloth before they draw the shutter, but some who have full confidence in their slides do not; consequently the inside of the shutter is exposed to the light while the plate is being exposed, sometimes for a long time before the exposure is made. Again, with the pull quite out of the slide shutters, the shutter itself is almost always fully exposed to a strong light, often, when waiting for an opportunity to expose for a long time. Many of these draw-out shutters are made of millboard, which is really a wood pulp. The researches of Dr. Russell tend to show that the inside of all shutters should be exposed as little to the light as possible, or an unsuspected source of trouble may arise.

SEIDLITZ P.O.P.

There is no doubt that the photographic trade is in a bad way. Even with the better summer there has been no improvement—indeed, I know of cases where trade is even worse this season than the last. Manufacturers, dealers, and photographers all alike complain; they are heavily stocked, with sales to speak of. I fear there will be sad times for some time very shortly. Even now purchasers can get almost anything at their own price, and in many cases far below cost. The fact is patent that there are far too many of every class engaged in photography to meet the present requirements. Opinions are much divided as to the cause of this. My own idea is that the boom was created by the amateur, and that the amateur's indifference to photography and his falling out of the ranks is the cause of the slump. There can be no denying that the amateur created the dealer in his present form. Very much of this state of things has been brought about by the "push-the-button-and-we-do-the-rest" photography that has been upon us. It was very different in the old days—I am speaking of the time of the birth of the gelatine plate—when every amateur strove to outdo others, and was proud of his work. Now almost every house has quite a number of cameras (of a sort) and things photographic, which have descended to little small children, who, knowing nothing of photography, produce awful monstrosities, and disgust of photography in everyone who sees them. Then we have only to look at the reports of the meetings of the various photographic societies to see how hard pushed they are for subjects to talk about. Now is this? Another generation has sprung up. Is there so much amusement and pleasure to be got out of photography if properly pursued as of yore? I believe they only want to take up to action to make them as enthusiastic as ever. Regarding plates, they may well be left to the manufacturer, except to the seriously-earnest few who pursue colour photography, there is little left for improvement—that is, in their present form—and they are extremely cheap and uniform. But there is another article in universal use which offered a greater scope for investigation and ingenuity than plates—that is printing paper.

As my purpose in writing this article is to endeavour to stimulate the waning interest of the members of photographic societies, I have worked out a formula, the components of which are to be found in nearly all households, with the exception, of course, of nitrate of silver. It is not an ideal emulsion. It will not give every tone from red chalk to black without gold or platinum, but with toning you can get all that most people require, and it keeps well. In short, notwithstanding its somewhat bizarre title, it is as good as some of the papers in the market; but there is plenty of room for experiment.

STOCK SOLUTION.

One Seidlitz powder, B.P.

Sodium chloride (table salt)	100 grs.
Best vinegar (free from mineral acid).....	1 oz.
Citric Acid	300 grs.
Methylated spirit	1 oz.
(or 2 ozs. of whiskey).	
Pure carbolic acid	30 grs.
Water that has been boiled and cooled ...	16 ozs.

Put the Seidlitz powder in a quart jug and pour the water upon it slowly so that it does not froth over; put in the citric acid and stir till dissolved, then add the spirit, vinegar, and carbolic acid; bottle, and label it.

Now, in coming to the making of the emulsion, I am in a bit of a dilemma with regard to the gelatine. The gelatine plays an important part; moreover, the quantity needed will vary with the quality and make. What is required is a good, clear, tough gelatine, not too brittle. I may not here advertise any particular maker. You can get gelatine from grocers and

chemists from about 1s. 4d to something like 6s. per lb. It is not very good at the lowest figure; you need not pay the highest by a long way; you must make your own choice. If you look in the store cupboard you will probably find a packet of "Nelson's patent opaque gelatine." The women folk make curious things of it, and—I am assured—eat them. Annex some of this. I have made enquiries, and find that you can get this gelatine almost everywhere, so, for this reason only, simply as a guide to quantity, I adopt this for the formula. I expect it will be fairly uniform.

To make a small but workable quantity of emulsion, put into a bottle or jar 180 grs. of gelatine and 4 ozs. cold water; let it work for half an hour at least, then place the bottle or jar in a saucepan containing water about up to the contents of the bottle. Heat the contents of the bottle to 120 degs. to 125 degs. F., with occasional shake or stir; remove from the saucepan and let cool. When the temperature has fallen to 100 degs. F. pour into the dissolved gelatine 1 oz. of the stock bottle solution, and mix well with the gelatine, then add silver nitrate (crystals) 30 grs. Shake till dissolved, and a little longer, and your emulsion is made, only needing filtering through clean, well-washed swansdown, calico, flannel, flannel-ette, or other similar material. Now, nitrate of silver in the presence of organic matter is very sensitive to daylight, especially when warm, so that the addition of the silver to the other ingredients and the following operations must be made in subdued light; candle, coal-oil lamp, or naked gas-flame will not hurt; the gas mantle will print your paper and de-grade your emulsion if at all near.

I think, all things considered, the best coating will be done by the beginner by floating, just the same as he would float albuminised paper. I have made for myself a small machine for experimental purposes with which I can coat a sample with a single ounce of emulsion, and use nearly to the last. This, of course, needs very careful weighing, which is not advisable for a beginner; besides, the above is a very cheap formula, and five ounces of emulsion is much nicer to work with. The ordinary purchasable dishes are very wasteful—better make one. After determining the largest size you intend to coat, get a sheet of glass one inch larger each way, and fasten upon one of its surfaces, at the edges—with Prout's glue, shellac, marine glue, or any suitable cement—four strips of wood one-quarter inch high to form a tray. Three-sixteenths of an inch fretwood is very suitable for the purposes. My own tray for experiments is only 11 in. by 9 in. plate-glass, the wood being stuck down with a thick mixture of shellac and spirit used cold, after "drying," two coats—drying between—of the same solution were given over the wood, extending over the glass a little. This has stood a good deal of wear, and is quite as sound as ever.

Of course this has been got ready before the emulsion is made. When about to coat put your emulsion-tray at one corner of a flat table or bench fairly level—a kitchen table does very well. Level exactly with three small wedges of wood your coating-tray. Have a string stretched across the room, and your paper ready to hand; cut half an inch smaller each way than the inside of your tray; filter your emulsion and pour it carefully into the tray to avoid the making of bubbles—I filter mine directly into the tray. At this time of year the temperature of your emulsion will now have sunk to probably 90 degs. F. Between 80 degs. and 90 degs. F. will do fairly well for this emulsion, coated this way. In colder weather a warm tank, or some such contrivance, will be necessary to keep the emulsion between these temperatures, unless you coat only one or two sheets, or are extremely nimble. Skim the top of the emulsion with the edge of a narrow strip of paper slowly. The strip should be a little shorter than the width of the tray. Hold one end in each hand, the strip nearly upright, and skim the emulsion with the edge, just touching the top, from

side to side, thus leaving small bubbles at the edge of tray where they will do no harm. Do not omit to do this between each sheet, for there are sure to be bubbles which you can scarcely see, but they would show plainly enough when you print your paper. Take up a sheet of paper by the opposite (diagonal) corners, face downwards, and bring the hands close together to convex the surface; lower it till it touches the emulsion from corner to corner, then bring down the hands slowly till the sheet floats upon the emulsion; tap it lightly a few times upon the back with the finger-tips from centre to edges to expel any air-bells that may be there, and make attachment complete, just as we used to sensitise our albuminised paper years ago. Now, this sounds all very simple, and so it is, taking less time to do than to write; but I think you will, with gelatine emulsion, find sufficient difficulty in obtaining an even coating, free from blemish, to make the operation quite interesting. Let the paper rest upon the emulsion about forty seconds if of ordinary thickness, when it will lie flat. Now take hold of the two corners nearest to you, and lift the paper—not too rapidly—from the tray, and with a dexterous movement let it fall, face uppermost, upon the bench or table to set. The quicker you lift the paper the more emulsion you take up, and the thicker the coating. Two or three sheets will give sufficient experience. It greatly facilitates this removal, saves the fingers from stain, and prevents damage to the coated surface, if, before floating the paper, you turn up at right angles an eighth of an inch the two corners you purpose taking hold of for removal. Repeat the operations till you have filled your bench. By this time your earliest coated sheets will have set. Hang these over a stretched string; if you do so that an equal length hangs over each side, it will still rest upon the line when dry. If badly hung you will probably find them on the floor, for they straighten out in drying. A kitchen, or any room that has had a fire in it during the day is very suitable for coating. The paper will dry in from half an hour to two or three hours, according to the thickness of coating and hygroscopic conditions. I have been very explicit, so that an absolute beginner may follow the directions, and not only improve upon the formula, but the working thereof. I know that the older hands will view with forgiving eyes my prolixity. My end will be attained if the prescription offered acts as a stimulant upon some of the members of our numerous photographic societies, which would ultimately redound to the benefit of manufacturers.

A. J. BROWN.

OUT OF THE PAST.

OUR Scottish readers will no doubt be interested in the following reminiscences which our confrere Dr. John Nicol published in last number of the "American Amateur Photographer" apropos of the receipt of the Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY:—

The Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY has for me such an amount of personal interest that, however absurd the reason, I cannot resist the temptation to give it an article altogether to itself. Of the three dozen portraits reproduced I was more or less acquainted with at least a third, and the intercourse with a few of them, if I could get space to tell it, would be both amusing and interesting. The other two thirds I am glad to see, as of most of them much has been heard and it is always an advantage to be able to correct our previously formed impressions, even although the correction be sometimes disappointing.

During the early sixties (I write too far from home to look up dates), my laboratory at 21, Dundas Street, Edinburgh, was a kind of headquarters for those interested in photography, a class considerably different from the average amateur of to-day; and there came together such landmarks, if I may use the term, as Talbot, Brewster, Burnet, Ponton, Horatio Ross,

Wilson, Walker, Davies, Tunny, Davidson, Bow, Piazzi Smyth, Hallard, Marrick, Raven, etc., etc., all or most of them members of the Photographic Society of Scotland. And it was consequence of certain features of that society that the energetic Edinburgh Photographic Society was formed. A number of the members of the older society were also Fellows of the Royal Scottish Society of Arts or other like societies. I knew that the discussions that generally followed papers were read elicited more information than was generally given in the paper itself, and as, for some reason or other, such discussions rarely followed papers read before the old society there was considerable dissatisfaction. It was hinted that papers by such big-wigs as Brewster and others like him, one cared to start a discussion, the result being that nothing beyond a vote of thanks to the reader was ever thought of and some of us wanted something more.

The result was that at a meeting in the room behind J. Taylor's little watchmaker's shop on the South Bridge, Edinburgh Photographic Society was founded, the date being February 20, 1861. There were present about ten, what would be here called "charter members," including Taylor, Burnet, Slight, Davies, Ramage, Muir, Valentine (of Dundee), of whom, so far as I know, only Slight and myself remain. J. D. Marrick, then Edinburgh City Clerk, now Sir James, was late Glasgow City Clerk, was the first president, and the society started with a degree of energy that it has never lost, having always been, and still is, one of the most energetic in Britain.

THE BRITISH JOURNAL OF PHOTOGRAPHY became the organ of the society—for a time, indeed, said so on its title page—the members were supplied with it at a reduced rate.

With Taylor I kept up a close correspondence up to time of his death, and in view of the claims that have recently been made as to his having joined the ranks of the spiritualists it may be of interest to record an incident that occurred shortly after he left London for New York. About that time I was one of ten who were holding weekly meetings in a vain search for evidence of the truth of spiritualism, and although we were open-minded, and some anxious to believe, and have the help of several mediums, including Duguid, of Glasgow, the evidence did not eventuate. One of the "anxious believers," a friend on a visit from India, with wealth equal to his credulity, on reading in an American newspaper a glowing account of the success of an American photo-medium in getting into his pictures the departed spirits of his sitters' friends, started at once for New York in the hope of again seeing a recently-deceased wife. And he was not disappointed. In less than a month he returned with a poor photograph, carte size of himself, and looking over his shoulder an over-exposed figure of a woman, flat but full of detail, in which he instantly recognised his late wife, and almost quarrelled with his grown-up daughter because she could not see it.

And now comes the pith of the story. Within a few days after the return of our Indian friend, now a confirmed spiritualist, I received a letter from Taylor, who, with a friend, had visited the same photo-medium and got, not a deceased friend of either, but what the medium called "one of his controls" and which contained a copy of the said photograph; and even a cursory examination of the two, the print got by our Indian friend and that sent by Taylor, showed unmistakably that both "spirit photographs" had been printed from the same negative.

But this is aside from the Jubilee Number about which I meant to write. Well, nothing that I have seen for many years has given me so much pleasure. Many of the faces altered, ah! how much since I last saw them—recall incidents long forgotten, but delightful when recalled. To those who like myself, were deeply dabbling in photography when Taylor, "B. J.," under its baby name, had its birth, it is an epitome of its progress, and a reminder of difficulties surmounted;

as entered the lists in later years it should be a source of management, and to every photographer, and many non-photographers, its thirty-two pages should be instructive and

ng. here all, or so much, is good, it is difficult to select, but we thank T. C. Hepworth for, in his article on "Journalistic Photography," giving credit to American magazines for priority in the production of half-tone blocks. Everitt gives a useful information anent lenses; my old friend Henderson is of ceramic photography, but, as usual, fails to say just how produced his own, certainly the best that ever left muffle; Emerson, well, he is as egotistical as ever, but has "the sage of his opinion" to an extent that enables him to repeat mistake of speaking disrespectfully of "gum," and saying it is dead, while he knows right well that it is daily gaining popularity, and that in the rooms of the Royal, of which an office-bearer, there is while I write an excellent exhibit altogether given over it.

at the ointment is little the worse of the fly, and the "B. J." Number should be a precious possession to all interested photography.

ere is one thing more that I feel a desire to set right. Wall, in speaking of "camera evolution," says: "Then the Kinnear or conical bellows, made first, I believe, by gher in 1861," but if any name is to be given to that at time popular camera it should be Thompson.

me time in the late fifties, Tom McKinley, a young man Liverpool, on a visit to his parents at Trinity, called on in connection with photography, and my attention was ected to a rudely-constructed camera he carried; because as the first bellows I had seen. Although very unlike the, ter known, Kinnear's, the description I was able to give to my friend Alexander Thompson, late Principal of the chants' Company's School in George Square, but then er in Dr. Guthrie's ragged school, set him a thinking and ructing, the outcome being the original model of the ra in question, he and I being joint owners, I having found material and he the invention and construction. We used camera a good deal, and it had so many advantages over ous landscape cameras that Kinnear, then one of Edin- h's leading architects, desiring to have one like it, showed James Bryson, then one of Edinburgh's leading opticians instrument makers, who copied it, and in a most workman- manner. Kinnear showed it at a meeting of the Photo- ic Society of Scotland, and a second was made for the D. T. K. Drummond, who, I believe, in his own genial way, the first to name it the "Kinnear Camera." That Meagher wards turned out many such cameras, I know, but not they were well known in Scotland, at least five being larly used in Edinburgh.

rious problems in solar research are soon to be studied on a of International co-operation. A plan was recently initiated ne Washington National Academy of Sciences, this body having oted a committee on solar research charged to consider the e question, and to ascertain the views of the astronomers, spectro- ists, and physicists, who in divers parts of the world, devote al attention to sun investigations. The chairman is Prof. George ale, director of the Yerkes Observatory, Chicago. At the St. s Exposition next month a general meeting of those interested e scheme will be held, when some attempt is to be made to out the lines of future work. At this gathering Prof. H. H. er, F.R.S., Savilian Professor of Astronomy in the University of rd, and president of the Royal Astronomical Society, will be ent, and take part in the discussions.

THE MERCURY VAPOUR LAMP FOR PHOTOGRAPHIC WORK.

[*"Scientific American."*]

THE mercury vapour lamp, unlike its rivals in artificial illumination, derives its light from the vapour of mercury, which is raised to a high state of incandescence by the electric current passing through it. The light produced by all of the other forms of electric lamps depends on the incandescence of a solid, which is sometimes carbon and at other times other material in the form of rods or filaments, as in the arc lamp, the incandescent lamp, and the Nernst lamp.

The accompanying illustrations (Figs. 1 and 2) show the

Fig. 1.—The Cooper Hewitt Lamp in the Photographic Studio.

mercury vapour lamps as employed in the photographic studio of Mr. E. C. Pratt, at Aurora, Ill. The illustration, Fig. 1, shows the Cooper Hewitt lamps in position for making negatives, the mercury light being used as a perfect substitute for daylight, while the illustration, Fig. 2, shows the frame lowered to the floor and being used as a printing lamp. Mr. Pratt states that he has made sittings at night with this equipment in the astonishing space of one second. The prints are made with the same light in from $2\frac{1}{2}$ to 10 seconds, according to the density of the negative, and the light only barely heats the negative, but not enough to damage it in the least. These lamps are constructed of glass tubes having metal sealing-in wires at each end. These wires lead the current to the electrodes, one of which

is of mercury, and the tubes are exhausted to a high degree by means of a vacuum pump and sealed off, preventing any escape of the vapour which fills the tube.

It is claimed that these mercury vapour lamps produce the most efficient electric light known, the current consumption being about 0.4 watts per spherical candle and, under favourable circumstances, it is stated as low as 0.3 watts per candle-power. Three ordinary 32-candle-power incandescent lamps required as much current as a mercury vapour lamp of 750 candle-power and the efficiency is therefore more than seven times that of the incandescent lamp and about double that of the arc lamp.

Fig. 2.—The Cooper Hewitt Lamp Used for Printing.

As the vapour is inclosed under a vacuum there is no consumption of the light-giving element and, therefore, this type of lamp requires no trimming.

The mercury vapour bath produces a light which is seemingly pure white, but is entirely lacking in red rays or nearly so, thus making it entirely unsuitable where the accurate determination of colour values is necessary. The mercury vapour lamp operates with absolute steadiness and without noise and is said to be the most desirable form of light for factories, machine shops, and work-rooms of architects and draftsmen, as well as for all classes of photographic work.

The light of this lamp is composed to a very large extent of

chemically active or actinic rays and is, therefore, a perfect substitute for daylight for all sorts of photographic processes. The use of this lamp the studio for portrait photography is located in any part of a building and the operator is independent of weather conditions. The photographer can devote his attention entirely to the artistic arrangement of light and shadows, as the time of exposure is constant at all times. The same equipment for the mercury-lamp skylight can be utilised for printing of all kinds with great satisfaction. The mercury lamp is of such shape that it is particularly well adapted for mechanical blue-printing with glass cylinders and revolving drums being, it is claimed, many times more efficient than a focussing arc lamp, while for photo-engraving work lamps of this type consuming eight amperes are said to do the work as quickly as arc lamps taking three times this amount of current.

FRANK C. PERKINS

A METHOD OF DETERMINING THE FOCAL LENGTH AND THE ABERRATIONS OF A PHOTOGRAPHIC OBJECTIVE.

[A Lecture given before the Royal Photographic Society.]

I.

I wish to show, in the first place, how the focal length of a compound lens—for instance, a photographic objective—can be measured, not only accurately, but also easily, and with a very simple apparatus, and at the same time to explain the rationale of the method. Secondly, I will show how the aberrations of an objective can be determined with the same apparatus. In connection with this I will suggest some aberration coefficients, which will give a numerical value to each. It seems to me that it will be of great advantage if the makers of lenses mark these coefficients on the lenses in the same way that they now mark the "numerical aperture" on the best microscope objectives. One frequently has to procure a lens for a special purpose for which freedom from certain aberrations is of great importance, while its behaviour in other respects is of comparatively small account. In landscape work, curvature of field is generally immaterial and may even be helpful by assisting in bringing the foreground into focus; in copying line drawings, on the other hand, a lens with a flat field is essential. For portraiture some amount of spherical aberration is frequently desired, but the lens should be well corrected for colour, and work at a large aperture. For process work it should not have a large aperture, as to obtain a correctly graduated dot it has to be stopped down to F.22, and at the larger aperture (used to close up the dots in the high lights) a slight loss of definition is unimportant. In this case the lens should be thin and have few surfaces in order that the loss from absorption and reflection may be reduced to a minimum. Many other instances will occur to everyone, and it is obvious that if the amount of the aberrations be known, it may be possible to substitute a cheaper lens, and still do work as good as or better than with a more expensive instrument.

FOCAL LENGTH.

There are certain very important fixed points in any optical system, lens, or mirror, after the man who first investigated them, Gauss points. These are the focal, principal, and nodal points. When light, from an infinitely distant point, passes through a lens along its axis, it converges to a point on its axis called the principal focus, or the first focal point. If the lens be reversed so that the light passes through it in the opposite direction, it converges to a point as before, called the second focal point.

For one position of the object, and only one, the image formed by the lens will be the same size and erect, then the object and image are situated respectively in the principal planes and these cut the axis of the lens in the principal points. The planes nearly coincide at about the diaphragm

the ordinary photographic lens, but are a long way off in the telephoto lens.

There are two other points which have a very curious property. When a ray of light falls on the lens, travelling in such a direction that if it had not been bent by the lens, it would pass through one of these points, then, after passing through the lens, it will emerge in such a direction that it seems to come from the other of these points. These are the *nodal points*. When the lens is working in air these will always coincide with the principal points. (The nodal points of a water or oil-immersion micro-objective do not coincide with the principal points.)

Fig. 1.—Home-made turn-table of wood. The upper board carrying the V's rotates upon the lower, round a pivot, which can be inserted in any of the holes.

I will now demonstrate this property of the nodal points. The light from a lamp at one end of the room is focussed by a large lens* upon a screen. The lens is mounted upon a board (Fig. 1) rotating upon a lower board, round a vertical axis, formed by inserting a pin through the two boards. There is a series of these holes in a line along the middle of the boards. When the pin is inserted in a hole at the end furthest from the screen, the image moves to and fro as the lens is rotated, going to the right when the lens is rotated clockwise. When the pin is transferred to the hole in the board nearest the screen, the image again moves when the lens is rotated, but in the opposite direction, namely, to the left, when the lens is rotated clockwise. Lastly, when the pin is placed in a certain hole near the middle of the board, the image remains stationary as the lens is rotated. This will be the nodal point, if the lamp used as the image is infinitely distant.

The explanation of these movements is clearly shown by means of a movable cardboard model. The *direction* of the ray from the distant lamp to the first nodal point, represented by a long stretched string An_1 (Figs. 2 and 3), is practically unaffected by the movement of the lens; so that the emergent ray

Fig. 2.—Cardboard Model of Lens. $n_1 n_2$ nodal points; C pivot; A n_1 incident ray; n_2 B emergent ray.

from the second nodal point n_2B , which, by the peculiar pro-

* A Berghem portrait lens of 6 inches aperture which was placed at the disposal of the lecturer by Mr. Dallmeyer, enabled these experiments to be made on a large scale, visible from all parts of the room.

perty of these points, remains *parallel* to the incident one An_1 , will move to and fro with the point n_2 . When therefore the lens is pivoted at a point C, the image will move to the right

Fig. 3.—The model rotated about C clockwise. The ray $n_2 B$ has moved parallel to itself with n_2 , so therefore has the image B.

(as one faces the screen) when the lens is rotated clockwise. When the pivot is transferred to D, the image will move to the left. Lastly, if the pivot is at A (supposing the lamp to be sufficiently distant), the image will be unaffected by the rotation of the lens.

The distance from n_2 to the screen will then be the focal length of the lens if the incident light come from infinity.

As the focal point is the point to which parallel light will converge, it follows conversely that light starting from this point, and traversing the lens in the reverse direction, will emerge as a parallel beam. Let this beam of light fall normally upon a plane mirror M (Fig. 4); then it is obvious that each ray will be returned upon itself, and after passing a second time through the lens, will converge again to F.

I can show this by passing the light from an arc lamp S, through a small hole, furnished with cross-wires, in a screen

Fig. 4.—Light from principal focus F_2 , emerging as a parallel beam, reflected back by mirror M, and reconverged to F_2 .

at F_2 . The light, after passing through the lens, is reflected back by the mirror, and, by tilting the mirror a very little, the image is deflected to one side of the hole, and can thus be observed. The distance is adjusted until the image of the cross-wires is perfectly sharp, and then F_2 is exactly at the principal focus of the lens.

REG. S. CLAY, D.Sc.

IRISH Lithographic Artists' and Photo-Engravers' Association.—The members of this society held their annual excursion on Sunday last, the rendezvous selected being the far-famed Seven Churches and Glendalough, which was reached after an enjoyable drive from Rathdrum via the Vale of Clara. The "Churches" and the Upper Lake and St. Kevin's Bed were visited, and many photographs taken. After tea the company resolved itself into a social, and several songs were rendered, and impromptu speeches delivered, in the course of which a well-deserved compliment was paid to the untiring secretary of the Association, Mr. Robert O'Flannagan.

NOTES ON RADIO-ACTIVITY.

[Abstract of a Paper contributed to the British Pharmaceutical Conference.]

I.

The property of radio-activity was in reality first discovered by Becquerel in 1896 for uranium-containing minerals and chemicals of every kind. The rays from uranium salts without the intervention of sunlight can be shown photographically to penetrate aluminium, bone, glass, black paper, etc., at a distance of several inches, and thorium nitrate (the constituent to the extent of 98 per cent. of Welsbach mantles) produces similar photographic effects.

Of late there has been much discussion as to the change that the radium atom is undergoing and the probability of uranium being its parent. Rutherford suggested that radium is analogous to the first bodies, designated uranium-X and thorium-X, resulting from the break up of uranium and thorium, and not to these elements themselves. I may here briefly outline the work on thorium. Thorium has long been known to be of a complex nature, and an American professor a little time ago caused some excitement by announcing that he had split it up into carolinium and berzelium. If ammonia be added to a solution of thorium nitrate the hydroxide is found on separation to have lost more than half its activity, whereas the filtrate from this hydroxide on evaporation to dryness possesses the bulk of the activity. This residue (the thorium-X soluble in NH_3) is minute, and weight for weight is 1,000 times as active as the original thorium nitrate. Now the precipitated thorium hydroxide regains its activity just as fast as the thorium-X loses it; furthermore, the activity of the precipitated hydroxide added to that of the thorium-X is always equal to that of the original thorium nitrate before the process.

Thorium-X loses its activity in a month. It produces an emanation, and this gas-like body changes into the matter producing the excited activity.

Similarly uranium yields a uranium-X, but this does not give rise to an emanation or to excited activity. As yet a radium-X is not known.

The position is:—

The amount of radium in pitchblende leads scientists to think that there is a direct relation between the amount of radium developed and the time taken to decay. It has been found that old uranium salts appear to contain more radium emanation than those freshly made. Many investigators are instituting experiments to watch the gradual development of radium in uranium salts and minerals. One worker calculates that the average life of the radium atom being 1,500 years (minimum), and the rate of break-up being in geometrical progression, $1\frac{1}{2}$ Mgm. ought to disintegrate per gramme in a year, or, if we take a maximum computation, 1/100 Mgm. would do so in this length of time. He proposes, therefore, to put on one side a few hundred grammes of freshly prepared uranium nitrate, and to examine for radio-activity in a few months.

Soddy² forestalled these results by finding the quantity was less than 10 — "Gm. in twelve months from 1 kilo. of uranium nitrate. Soddy and Ramsay (*ibid.*) showed that less than 1/1,000 part of radium changes per annum, and the rate of change of uranium may be assumed to be one million times slower, therefore 5×10^{-7} Gm. of uranium nitrate would change per year. Soddy concludes that less than 1/10,000 part of the theoretical quantity is formed in the first year, and inclines to the belief that uranium is not the parent of radium.

An American investigator³ found an agreement between the quantity of uranium and of radium present in certain ores. Joly⁴ inclines to the view that radium may be an atomic combination of radio-

active products with some of the heavy metals in pitchblende. He would therefore represent the synthesis rather than the disintegration of an element. He instituted experiments in July to test the yield, if any, of radium emanation by artificial chalcocite (uranium copper-phosphate). Simultaneously pure uranium nitrate and impure uranium nitrate (crystallised with small quantities of heavy metals) were put under observation. Strutt⁵ found the proportion of radium and uranium in minerals constant, e.g., copper uranite dissolved in sulphuric acid gives an amount of radium emanation about equal to that yielded by the same weight of Joachimsthal pitchblende; the percentage of uranium is also about the same.

Radium has undoubtedly been produced since the formation of the mineral; Ramsay and Soddy's determination of the rate of production of the emanation proved this, and Strutt claims that this proves that uranium must be the parent of radium.

In considering a few particles of radium we realise that most of the atoms behave as if they were permanent. None of them are, of course, really so, though only very few are breaking up from moment to moment.

A writer on the subject⁶ imagines one in every million billion atoms of thorium to throw out per second a fraction of its mass, i.e., the alpha-ray, the remainder of that atom, becomes the thorium-X—this again throws off another part of its mass, becoming the atom of the emanation—this changes into the matter producing excited activity, and so on. It would take at least a million years for 1/1,000 part of the mass of thorium or uranium to be changed. The activity of radium being 1,000,000 times greater than that of thorium, about the same proportion of this body changes as of thorium; in other words, according to this author, the life of radium is not more than 1,000 years.

In the case of radium it is suggested by Rutherford⁷ that after the emission of the alpha particle the rest of the radium atom is radium-X; this then disintegrates into an alpha particle, and the emanation, which latter in turn breaks up, expelling more alpha particles and changing into the matter which causes excited activity; the final product being perhaps polonium, the radium "atom" consisting, therefore, of the polonium atom and about six alpha particles, but these, when their charge is neutralised by a negative corpuscle, are believed to become helium atoms, with the result that the radium compound radical would have the formula PoHe . Polonium has, however, I believe, been obtained free from radium (spectroscopically).

Soddy⁸ states that 25 per cent. of the entire alpha radiation comes from the radium and the remainder from the emanation and the matter causing excited activity.

ATOMIC WEIGHT.

Madame Curie's figure of 225 may require confirming, the spectroscopic value being 257.8, but the former figure still has its supporters. A recent writer in "Nature"⁹ pointed out in detail certain defects in the spectroscopic calculations; his corrections place the theoretical value nearer 225 than 257. Madame Curie placed radium in the Mendeléeff Periodic Law after barium, with the alkaline earths in the row already containing uranium and thorium. Naturally there arose a great controversy among the various schools of chemical belief as to the position that radium should occupy. Mendeléeff for one¹⁰ was not inclined to the disintegration theory. In endeavouring to fit in argon and helium and the other new elements in his periodic system he came to the conclusion that the "ether" itself must be atomic, and be placed in the argon and helium group, and he offered the opinion that the energy of radium, its light and electrical properties, were simply due to the emission of the ether atoms.

RAYS.

The radio-active elements are by most scientists regarded as slowly breaking up, and at a definite uniform rate for each individual body. This takes place in stages, the emanation of radium and thorium and the active matter resulting from further change of the latter causing induced activity, are transitional forms between heavy and light

order of the above is of no particular moment, and they are ts to be read downwards. Every electrical current may be red a continuous stream of electro-negatively charged electrons. case of radium these electrons ionise the air and produce ally oxides of nitrogen and ozone; this is probably an im- hard" X-ray tubes the vacuum is very high and the electrons correspondingly enormous velocity, hence the greater sudden- the stoppage of the stream and the greater the penetrative produced. The α -rays (very slightly deviable in a magnetic constituting about 99 per cent. of the entire radiation) are cut o half value by passing through a sheet of aluminium, 0.0005 ick; the β -rays by passing through 0.05 Cm. of Al, and the y passing through 0.8 Cm. of Al.

ame Curie found that a singular law of absorption existed, , that the absorability of the rays increased with the thick- the matter to be traversed, i.e., between the limits 1 to 6 hat a screen of lead 1.8 Cm. thick transmits 2 per cent. of the on it receives, and a screen of 5.3 Cm. thick transmits 0.4 per of the radiation it receives. The alpha-rays are about 1,000 the mass of the cathode ray particle. They have a velocity th that of light, i.e., they travel at about 20,000 miles a

ral simple experiments can be shown to demonstrate the g power of these alpha particles by collision with the neutral les of a gas; they tear them asunder into ions. It is a very able thing that in the case of polonium we have alpha-rays t any beta-radiations; this is difficult to conceive. demonstrate the α -rays the zinc-sulphide screen is far the most ve.

BETA-RAYS.

be hundred million atoms would lie side by side in an inch, ectrons are one thousand million-million times smaller than the of hydrogen. These are the atoms of electricity, and they are ous with the cathode rays, but differ in that they are projected ace. Madame Curie states the intensity of the β -rays varies the thickness of the radium layer. The most powerful cer for this type of radiation is native zinc silicate, which is as willemite.

GAMMA-RAYS.

se are in all probability X-rays resulting from the bombard- of the radium substance by the β -electrons. They result directly the radium and not as a secondary effect. They are, it is ed, generated at the moment of expulsion of the α and s, and they are always proportional in amount to these. These as shown by Madame Curie, traverse several centimetres of

marked difference¹² has been observed, however, between the e conductivity of gases for the γ -radium rays and the X-Rays. e former Strutt showed that the conductivity varied directly

with the density, but in the case of the X-rays there is a marked divergence:—

	Density.	γ -Rays.	X-Rays.
Air	1.0	1.0	1.0
Carbonic acid	1.53	1.53	1.6
Sulphurous acid.....	2.19	2.13	7.97
Chloroform	4.32	4.88	31.9
Methyl iodide	5.05	4.8	72.0

Another investigator in "Nature" finds that these differences narrow down if the comparison is made with a "hard" X-ray tube, so that the difference seems to be one of degree rather than kind.

The γ -rays can be well shown with a large crystal of barium or lithium platincyranide.

A useful application of the ionising effects of radium has been devised by a worker¹³ at the botanical laboratory in Dublin, namely, to prevent the electrification of sections cut in paraffin, their adher- ing, curling up, etc., a tube of radium may be fixed on to the micro- tome knife with very satisfactory results. There are many applica- tions of this kind which will doubtless be developed as the material becomes more common.

THE EMANATION.

This gaseous body, which can be passed on from one vessel to another, and which can be condensed by low temperature into solid or liquid matter, was in the early days the subject of considerable confusion with the radiation. It is strongly radio-active, and as has already been described is unstable.

Rutherford claims that a cubic inch would probably melt a glass tube containing it, and as it possesses three-quarters of the power of radium a few pounds of it would drive a ship across the Atlantic. Seventy tons of radium would, however, be necessary to produce each pound of emanation.

Ramsay and Soddy found helium occluded in cleveite and other radio-active minerals. They watched the gradual development of the helium spectrum in a sealed tube, in which the radium emana- tion was originally condensed by the aid of liquid air. It has been suggested, but not yet conclusively proved, that the alpha particle is an atom of helium. These investigators¹⁴ conducted elaborate experi- ments with the object of ascertaining the volume of emanation emitted by radium, and also the amount of helium resulting from the change. One of their statements is to the effect that 50 Mgm. had produced 0.1 cubic Mm. of helium in sixty days; this quantity weighs 0.000018 Mgm., hence 1 Gm. of radium bromide should give 0.0022 Mgm. per annum. They also claim that only one atom of emanation can be produced by one atom of radium, and that only one α -particle is expelled at each disintegration.

Moss has recently conducted some experiments, the results of which indicate that helium probably exists in pitchblende in the free condition in minute cavities.

The mineral Kunzite is illuminated under the influence of emana- tion, but does not respond to α -rays. Soddy explains that this illu- minates that the emanation only gives α -rays, and that the β -rays are only produced when some of the emanation has changed into the matter causing the excited activity.

HEAT.

The heat energy from 1 Gm. of uranium oxide had been estimated in 1901 as at least 0.03 calorie per gramme per annum. However, when multiplied out by one million this does not accord with the present estimate of the heat emitted by radium, which is at the rate of 100 Gm. calories per gramme per hour. More than two-thirds of the heating effect is not due to the radium at all, but to its emana- tion, and to the product of this latter body. Another statement of the theory is that the heat is due to the radio-active substance being bombarded by its own α -rays. It is possible that by combining these disintegration products at a high temperature the synthesis of radium may yet be achieved.

THE FRANKLIN INSTITUTE AND THE "KODAK" DEVELOPING MACHINE.

[Abstracted from the "Journal of the Franklin Institute,"]

THE Franklin Institute, acting through its Committee on Science and the Arts, investigating the invention of Arthur W. McCurdy, of Toronto, Canada, reports as follows:—

The awkward tendency of photographic roll-films to curl up in the process of development, the consequent handling required and undue exposure to the dark-room light, have led the manufacturers of this product, the Eastman Kodak Company, of Rochester, N.Y., to place on the market a device with which development can be carried on without the aid of a dark room and without any handling of the film whatever until it is developed and fixed.

The apparatus is adapted to treat what is known as "daylight film," that is, film covered in the back, its full length, with a strip of black paper before reeling to enable it to be inverted in the camera and removed from it in daylight without injury.

The most obvious method of reducing the amount of handling required to develop each separate picture is to develop the entire film at one operation—a practice of no very recent date among professional operators. A simple apparatus for doing this would consist of a cylindrical roller placed at the bottom of the developer recipient under which the film, face outward, could be drawn back and forth. Enlarge the roller until its circumference is equal in length to the film to be developed, provide means for attaching it thereto, at the same time keeping it tightly drawn against the surface, add a crank for rotating the cylinder and a light-tight cover, and we have the Kodak developing machine in its most elementary form.

A cylinder large enough to hold a film of the usual length would be inconveniently large, and in the perfected machines it is replaced by a flexible strip of celluloid somewhat larger than the film with a strip of corrugated rubber along the full length of each edge. When this is rolled up it forms a spiral with a space between the adjacent coils equal to the thickness of the rubber edging. If the film is rolled along with it, face outward, it occupies the same relative position with respect to the spiral surface as it did in the previous case with respect to the cylinder. This may be mounted on a mandrel and submerged in the developer which finds its way through the corrugated edging between the convolutions of the spiral to the film surface.

After describing the machine the report goes on to observe:—It may be questioned whether treating exposures made under widely varying conditions in the same developer for the same time would not result in many failures. "The manufacturers claim that by using the developer they recommend, pyrogallie acid, great latitude in exposure is allowable.

"Three six-exposure films, exposed by the Kodak Co. were developed according to their printed directions. The subjects are outdoor views taken, probably, under one condition of lighting. The excellence of the resulting negatives, submitted herewith, demonstrates without doubt the capabilities of the device for normal exposure.

"To further test the machine with varying exposures, three indoor exposures of the same subject were made of five, ten, and twenty seconds on a film containing 'snapshot' outdoor exposures. The results were perfectly satisfactory and leave little doubt that great latitude in exposure is allowable.

"For the excellent performance and certainty of action of the machine and the ingenuity shown in devising the simple and efficient means leading thereto, the Institute recommends the award of the John Scott Premium and Medal to the inventor, Arthur J. McCurdy."

THE INTERNATIONAL SOCIETY OF PICTORIAL PHOTOGRAPHERS.

We learn from "The Photographer" (New York) of the formation recently of an International Society of Pictorial Photographers, somewhat on the lines of the well-known Photo-Secession organisation of America, but with several minor differences. Craig Annan, of Glasgow, Scotland, is the president, Alfred Stieglitz first vice-president, Kuehn of Austria second vice-president, while on the board will be Demachy of Paris, Keiley and Steichen of New York, Henneburg of Vienna, Juhl and the Hofmeisters of Hamburg, Hinton, Evans and Craigie of London and a few others of equal prominence. The society will hold an international show in New York in 1905, which will be managed locally by the Photo-Secession.

RAYS OF LIGHT FROM THE HUMAN BODY

RECENTLY photographs have been made in an absolutely dark room of rays from the human body. Not man alone, but all matter, has proved to be constantly engaged in a process of absorbing waves of varying lengths and of giving out waves of a definite length. These emanating waves are characteristic of the matter that emits them.

These waves or rays were discovered and photographed made a discovery in the laboratory of Professor Arthur W. Goodspeed, Randal Morgan Laboratory of Physics of the University of Pennsylvania. Professor Goodspeed, who discovered them, gave the results of his researches to the scientific world in a paper read by him before the American Philosophical Society on the night of May 15.

While only the threshold of the discovery has been passed, suggestions have come from many scientists concerning the practical application of this discovery. Of these suggestions, the one most frequent is that physico-radiographs of the rays from individuals may show the physical condition of the subject.

The experiment that directed Professor Goodspeed's attention to a new line of investigation, and that resulted in the discovery of the new ray, was made on April 6 of this year.

He was photographing with X-rays on that day, and used for support for his photographic plate an iron-tripod stand with the plate at its top. The plate rested in its box on this ring, with the film face upward. The rays were directed downward upon the plate. Professor Goodspeed developed the plate he was astonished to find that the action of the X-rays had been influenced by the ring.

He next placed a wide bronze ring between the rays and the plate, retaining the iron ring as a support. This radiograph, when developed, showed a darker shadow just above the iron ring and a lighter shadow where the bronze overlapped.

Numerous experiments with other metals and with the rays in various positions followed. Each metal was found to have a characteristic effect. It was also seen that the effect of the radiant influences from the several metals was to reach around the shadows of objects impervious to the X-rays. The influence was directed in a direction opposite to that of the rays from the tube.

After a number of experiments in which the rays from the Crookes tube were directed downward, and were intercepted by impervious substances before reaching the photographic plate below, Professor Goodspeed devised the apparatus with which he has made all his recent startling experiments.

Upon the light-proof black box containing the Crookes focus tube in operation, he placed a pile of lead plates. The X-rays were directed upward. The lead plates, being impervious to the rays, reflected them so that they passed out from the bottom and the sides of the box.

Upon the heap of lead was now placed a light-proof box containing a photographic plate with the film side upward. This was capped by a brass cylinder having neither top nor bottom. A small aperture was in the cylinder's side.

When all things were in readiness for the experiment, the focus tube, ring, and a piece of aluminium were placed on the lid of the box containing the film, and the top of the cylinder was closed by a heavy piece of zinc. Professor Goodspeed then stood about 2 ft. from the box containing the Crookes tube, and held his hand over the aperture in the brass cylinder, and about 3 in. from it, maintaining this position for three minutes the plate was developed and was found to show remarkably clear radiographs of the objects that had rested upon the lid of the box.

The focus tube is a glass globe from which the air has been exhausted. A concave receiver within the globe collects the rays that are generated by an electrical apparatus, and casts them against a platinum plate. This transforms them into X-rays.

The rays passed out through the box into the body of the subject, and were transformed within the body into the characteristic human ray. Passing out of the body, they were directed upon the box containing the photographic plate, and influenced the film. In another experiment two apertures were cut in the cylinder. Before one of these Professor Goodspeed held his hand for several minutes. The other opening was unobstructed. Development of the plate showed a broad, brilliant band of light flowing from the tube that had been opposite the hand, while a faint, brush-like mark marked where the unobstructed opening had been. It was

probable that the faint light was caused by rays coming from Professor Goodspeed's clothed body.

In a third experiment one of the apertures was closed with a tiny piece of glass and the other left unobstructed. The rays from the one and passed with comparative difficulty through the glass. A fourth experiment showed that aluminium was more translucent.

"Is it possible that these rays may be so intensified by a Crookes tube or other apparatus that they may be seen by the human eye?" Professor Goodspeed was asked.

"That question must be answered by future experiments. It is altogether probable that to the sharp eyes of certain animals man is made visible in a dark room by the rays from his own body. This may explain how some of the animals see in the dark.

"I made another discovery in the course of my experiments that will be of especial interest to scientists. That is the cause of X-ray burns the human body.

"While experimenting with X-rays about a year ago I kept the Crookes tube in operation almost constantly for a week. I not only worked in the room by day, but slept in it at night. About the third day an attack of conjunctivitis developed in my eyes, and gave me so much trouble that I could scarcely work.

"While at work on these later experiments, I again worked day and night in the laboratory, and again I was attacked by the mysterious affections of the eye and throat membranes. With the knowledge that I had as to the result of the radiographs made by the rays from my body, I concluded that the absorption and transformation of the X-rays by the body caused the trouble. The symptoms in both experiences were identical."

Commercial & Legal Intelligence

THE Brooks-Watson Daylight Camera Co. advise us that it is their intention to make their London Offices 119, High Holborn, W.C. (corner of Southampton Row), the chief centre of business on and after September 1. All communications respecting the business of the firm should be sent to that address on and after this date.

REMOVAL of the Optical Branch of Houghtons, Ltd.—This branch of the business of Houghtons, Ltd., has been removed from the old premises formerly occupied by Messrs. Joseph Levi and Co. (97, Hatton Garden), to more convenient premises close by. The new show rooms are now ready, and all letters for the Optical Department should be sent to the new address in future, No. 95, Hatton Garden, E.C.

A TRAVELLER named William B. Williams employed by Mr. Charles Hood, of St. Martin's Lane, was last week fined £10, with the alternative of a month's imprisonment, on a charge of embezzling £5 8s.; belonging to his employers. Williams was said to have obtained orders from Miss Vesta Victoria, the variety actress, for photos and posters, the account being £13 8s. Without disclosing the extent of the business done with Miss Victoria, he paid two sums, £5 and £3, to his employer "on account," representing the account to be £12 12s. He then disappeared for a week, arriving at the office again on August 6, when he was told that it had been ascertained that the account was fully paid.

MESSRS. R. AND J. BECK, LTD., of 68, Cornhill, London, E.C., have instituted a novel and at the same time efficient coupon system by which the owners of Beck Symmetrical or Beck Double Aplanatic lenses can obtain by a well thought out plan of exchange, plus cash, one of the new Beck-Steinheil Unofocal Lenses, to fit their cameras. The system offers the double advantage that the possessor of the cheaper lens can get practically full value for it, which he would hardly expect in the ordinary course of sale, and is at the same time enabled to obtain for his camera one of the best modern Anastigmats with but a reasonable outlay of cash to the difference. Full particulars of the scheme will be supplied on application to the above address.

Exhibitions.

THE FALMOUTH EXHIBITION.

THE Royal Cornwall Polytechnic Society, of which the headquarters are at Falmouth, is one of the oldest of the provincial scientific societies in the Kingdom, and it has done a great deal of good work in encouraging invention, scientific development, arts and crafts, the fine arts, and photography. Last week there was held the sixty-ninth exhibition. These were annual until a few years ago, and are now held biennially. The photographic section has always been a strong and popular one, both with exhibitors and visitors, and in the later years has kept well in line, though so far removed from metropolitan influences, with the more important exhibitions elsewhere. For many years this section has been under the care of Mr. Wm. Brookes, but these duties have on the present occasion been undertaken by Mr. H. W. Bennett, well known as a photographic worker.

For many years the number of pictures at Falmouth have been too many for the space available—that is, to do the subjects justice and to permit of any degree of scope in hanging and arrangement. Of course the management desire, and the public may like, a big show. The present is smaller in number than usual, and perhaps on the whole smaller also in average size of each individual exhibit; but the quality throughout is excellent, and the collection is a very enjoyable one.

The schedule, we understand, is somewhat complex and greatly divided, but the exhibition perhaps differs from all others—or most—in that the walls show no indication whatever of classes or divisions. This has been so for many years, and therefore this is no new departure in this case. But it gives the public no idea whatever what the competition was like nor how the awards compare with each other. Such comparisons will always arise, and of course here there is no evidence but that the pictures were judged as they are grouped on the walls. The exhibition is simplicity itself—in the walls and in the catalogue; in the latter there is simply evidence of professional and amateur work. We venture to submit that in future the distinctions that are missing from the walls and the catalogue be made actual, and that there be no classification at all. Awards could still be made for good work and artistic excellence. The management of the section has not, apparently, been able to get over the trouble that has existed at Falmouth for many years, the scattered hanging (as compared with the works of an exhibitor and the numbering of the frames) which makes it extremely difficult, if not impossible, to find the whole of an exhibitor's work and to do him justice in one writing. In the catalogue his numbers usually follow consecutively; in the room his prints are exasperatingly widely apart. This has always been so at Falmouth, and we cannot understand why there might not be an attempt towards grouping, in a limited degree, at any rate. It might be understood when the hanging is in the care of persons of conservative tendency, with traditions of "our way is the best," but this year the whole section is in new hands, in touch with modern ways. It is, of course, not always easy to do the most desirable thing, especially if circumstances do not readily lend themselves to it. People go to an exhibition and buy a catalogue, largely with the hope of being able to pick out and readily find a man's work. By the system of hanging adopted there are necessarily innumerable hunts to find what is wanted. We have again and again drawn attention to the way the pictures are arranged at this exhibition—trying to the ordinary person, but doubly so to the pressman who wants to do the thing properly—and we hope that at the next exhibition a better state of things will be found. There is, after all, nothing but congratulation for the arrangement and taste exhibited in hanging; but this could also have been secured with a better attempt to serve convenience.

So far as the catalogue is concerned, as we have pointed out, there are two classes only; but so far as the exhibition is concerned there is confusion of the most pronounced sort. We are by no means sticklers for close classification, or, for the matter of that, of any classification at all if there is a good standard, but in an exhibition that is classified the exhibits in each class should surely be under separate heads, and, when looked for, be findable under that head.

It would be far better for the executive to throw overboard (the harbour at Falmouth is a big one, and no harm would be done) the pretended classification, and have none, for as it stands, so far as the public can see there is no differentiation between the professional work and the amateur. The exhibits are all lumped, and we cannot therefore deal with the classes in a proper way, nor with each person's exhibits together, because life is not long enough to find them and put them together mentally for comparison, and get through the job in the time at command. It may be said that, so far as may be judged, there is no wide disparity between the work of the professional and the amateur. In the matter of total the latter has the best of it. There are a number of small prints, and the tints are mostly of brown. The exhibits being fewer than usual, the exhibition is much more comfortable and enjoyable, and the hanging really has had a chance, as it has not had for some years. It is true that formerly the walls were well covered, and were not so much a disturbing element as they are now. The room is not beau ideal for a photographic exhibition, but it is the only one available, and tradition has to some extent set it aside for the work.

We think the best way will be for us to take the exhibits as they came on the walls and comment as we go, and if mention is made of the same worker more than once, the reason will be understood.

Wm. Norrie contributes an interesting series of prints taken on a scientific cruise in the yacht "Day Dream" in the Faroe Islands (824), depicting whaling scenes, villages, and some landscapes, which are very valuable and interesting as showing the geological conditions of a very striking coast. The work is very well done. Wm. Lidgley secures a first silver medal for a fine bit of flower photography, "Roses" (enlargement), in which is fine rendering of half-tone and good gradation. The pictorial quality of the subject might have been increased by the elimination of the very thorny and unsightly branch which, while quite true to nature, seems redundant. Mrs. Annie Blamey, under the absurd (even if literal) title of "Two Enlargements" (881), shows a couple of interesting studies of ponies with a small boy in attendance, who is occupied in looking at the operator. The work is good. W. G. Garland's "A Bite" (810) depicts three boys of a seaboard parish who stand on the edge of a rough quay, one of whom has cast his line into the waters below. The arrangement of the figures is excellent, and there is no suggestion of pose or stiffness. Gertrude Boyns may be congratulated upon a very fine subject in "Carting Seaweed during a Gale, Bigbury Bay" (807) but the exposure was, apparently, too short, resulting, in this (enlarged) print of too strong colour. The pictorial quality is, however, highly commendable. D. W. Kyle's "Pæonies" (816) is in every way, selection and technique, a very fine bit of work, worth, it might be supposed, the second silver medal it has secured, or even more. But the pronounced grain of the oak mount is a bit too strong for the print, and it has paid the penalty. Evan Griffiths has contributed what is really a very uncommon incident, "Shooting Wild Duck" (885), in which the sportsman, the wild duck, and the dog are in proper relation, and go to make up a very interesting photograph, in which the arrangement is by no means bad. F. W. Beken's "Lee Rail Awash" (828), a very clever yachting study, full of go and very pictorial, has very deservedly won a first bronze medal, and might well have had something better, considering the difficulty of the subject and the good technique. A fine study of yachting in a gentler breeze, by the same hand, is "Close Hauled" (829). W. L. F. Wastell's "The Toilers" (888) is a ploughing scene, with an accurate suggestion of movement, and a sense of good arrangement. The same exhibitor's "The Pavement Artist" (895) is a clever piece of work, children watching the artist, and all unconscious of the presence of the photographer. There is much pictorial quality in two little scenes, "Ploughing study" (899) and "On the Thames" (893)—the latter very reminiscent of W. Thomas's work—by the same exhibitor.

D. W. Kyle's "Begonias" (815), while excellent in many respects, is hardly equal to his "Pæonies." M. G. Garland's "Evening—Low Tide" (811) is somewhat pictorial, but would have gained greatly by cutting down and a somewhat subdued foreground, the wet mud being stronger than the glow in the western sky. E. Seymour's "Interior of St. Alban's Abbey" (823) is a very creditable study of

interior architecture. C. H. Dymond's "An Anxious Moment" (9) a study of boys engaged in a game of marbles, is perhaps the best of his contributions, and its quality suggests an award. His "In Roar of the Sea" (802) is a really fine pictorial snap of tumbling, heaving sea breaking in a rocky cover. It would gain by being presented in much larger size. Wm. Lidgley's "Daffodils" (917), while untrue to Nature and good technical photography, just wants a touch of poetry. A. G. Kimber's "A Priory Stairway" (806) is a very clever architectural study, soft and delicate, and of just the right colour, but is somewhat marred and the general repose disturbed by the strong lighting of the stair-rail. G. Hepworth's "Door of South Transept" (957) is a very interesting bit of work but rather lacking in interest and gradation, which is a little strong lighting would alter. More pleasing and enjoyable is his "Entrance Porch, Newburgh Priory" (958), which is admirably chosen as the work of fine technical excellence. Harry Case wins a second silver medal with "A Study" (900), a very fine example of at-home portraiture, a lady seated on a carved bench near a mullioned window, the lighting admirably done and the textures of fine quality; posing is altogether natural. For "Crypt, Winchester" (955), W. Clarke has secured a first silver medal. It is true there were great difficulties (and a very long exposure involved, probably), but we can hardly see the reason for this award. His "Ely" (953) a "Across the Choir, Ely" (954) are, either of them, surely, quite deserving. It may be rank heresy to say so, but the delightful little quarter-plate landscape that hangs below it, "A Woodland Stream" (892), W. L. F. Wastell, is equally deserving. It is altogether charming and enjoyable. John H. Gear's "Rigoleur" (80) a jovial monk laughing, is certainly a good thing, natural and easy in pose, and, as may be supposed, of good technique, but we cannot quite find reason for the award of a first silver medal which it has secured. E. Seymour's flower studies are very good; probably the best of them is that of pelargoniums, "Flower Study" (820). "White Rufus Sleeps" (956), sombre in tone, as befits the title, by W. Clarke, is a clever study of a cathedral interior. R. Burley Mosley's "End of the Day" (913), a farm team going home, is good photography, and with pictorial quality. B. Ward Thompson's "Mile Hills" (944) is unhappily titled, surely. It is a mass of hills and a study of such and a big lake, but the elements are disturbing and do not make for agreeableness. It is rather a painter's subject, and is not a success as it stands, though it certainly is, in a way, commanding. E. J. Jarvis's "The Light of Peace" (963) is a fine study of a modern man-of-war (is the title ironic?), almost in silhouette, with a strong sky and brilliant glint of water. It is a downright good thing, of fine technique, has much pictorial excellence, and might well have had a high award. The same exhibitor's "After toil, a friendly port" (964) is a study of small craft in an open harbour, and very interesting. B. Ward Thompson's "Surface dappled o'er with shadows" (937) is a charming river landscape, perhaps a little flat in treatment, but attractive as a subject. W. Morley Martin is a specialist who is doing some exceedingly useful and high-class work in radiography and is awarded a first silver medal for a splendid series illustrating "The Evolution of the Common Frog" (945). This is work which is deserving the fullest recognition by such a society as the "Royal Cornwall Polytechnic." He is also represented by a series of twenty-one prints illustrating "The Embryology of a Chicken" (946), and a series showing the "Radio-activity of Cornish Pitchblende," from which the best radium is made. F. Martin Duncan is represented by a sea-water aquarium subject. "Duel à la mort" (818), a fight between an octopus and a crab, and one of the cleverest and most instructive things in the exhibition. Of course, it has not an award as difficult as was the subject to handle. He also shows "Studies of a Chameleon" (819), work of the best quality. F. W. Beken's "Doorway, Romsey Abbey" (830) is a very excellent presentation of fine Norman work, of fine technical quality. Mrs. Annie Blamey contributes in one frame six very fine examples of "Hand-camera work" (883), two of which, shipping and a pacht, have much artistic merit. S. G. Kimber's "A Woodland Pathway" (905) has considerable charm, but the mid-distance becomes too suddenly diffused, which tends to mar the rather charming foreground effect. B. Ward Thompson's photographs of "Old English Lustrous Ware" (931, 932, 933), are exceedingly meritorious, for the photo-

y of glossy pottery is a very difficult subject, and not easily red. J. W. Smith has a rather good lot of "Architectural ings" (867), some of them greatly marred by unsuitable mount- Rectangular and oval mounts in the same frame, with archi- tal subjects, is one of the best possible ways of doing such ings in justice. G. Hepworth's "Entrance Porch, Farnley Hall" is a very fine subject splendidly handled. B. Ward Thompson two very fine waterlily subjects in "Here rushing down the ing rocks" (934) and "Down the valley rushing" (940). W. H. e has secured a first bronze medal for "Softly falls the golden (927), a quiet, reposeful, and clever study of a cathedral or h interior, the difficulties of which have been well surmounted. South Porch, Truro Cathedral" (926) is impressive, and work e highest technical excellence. "Twilight" (887), by W. L. F. ell, is a river study, a barge on a beam wind, with considerable uted movement in the water and a soft grey evening tone. A enjoyable print, to which a second silver medal has been ed. John H. Gear's "Fenland" (801) is an evening study, low e, and of good technique.

e arrangement and management of the section was in the hands r. H. W. Bennett, who must be complimented upon having done all under the difficult circumstances of the case. He also acted ge, and in this was associated with Mr. J. H. Coath and Mr. Taylor Carne.

r. J. H. Coath sent a fine lot of prints, which were not entered competition, and which do him justice as a good photographer as one having a great command over children and animals. ing the works deserving of mention are "Study of a Lady" (835), "Study of Cats" (844), which is very fine; and a "Study of Ducks" . If Mr. Coath's work had been in competition, he would ably have scored very thoroughly.

FORTHCOMING EXHIBITIONS.

September 14-15.—Cambridge Photographic Society. Hon. Sec., Scowdon, "Sunny Side," Guest Road, Cambridge.

September 16 to November 5.—Photographic Salon, Dudley Gallery, St. Martin Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-ninth Exhibition, New Gallery, Regent Street, London. Secretary, W. W. Bartlett, 66, Russell Square, London, W.C.

October 15-29.—Coatbridge Photographic Association. Hon. Sec., W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

October 19-22.—Rotherham Photographic Society. Hon. Sec., H. Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, C. B. Appleby, Barnbygate House, Newark.

November 2-23.—Plymouth. Hon. Sec. Photographic Section, J. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, Frederick Street, Sunderland.

November 17-18.—Braintree and Bocking Camera Club. Hon. Sec., W. H. Tilston, 81, High Street, Braintree, Essex.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Valé Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Park, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

New Apparatus, &c.

Watson's Patent "Antinous" Shutter Release. Sold by W. Watson and Sons, 315, High Holborn, London, W.C.

A new pattern of this excellent substitute for the familiar ball and tube release for photographic shutters has been put on the market by the patentees, Messrs. Watson and Sons. This pattern differs from its predecessors in the method in which the release is applied. It is adaptable to practically any shutter or camera where the release is effected by downward pressure of a trigger. For instance, it can be fitted to one of the Bausch and Lomb automatic shutters, or to one of the various forms of magazine hand cameras the shutter of which is worked as above mentioned. This new pattern of release is also available for the shutters of cartridge kodaks and

other small hand cameras, for which Messrs. Watson propose to supply it with a reduced length of 9 in. instead of the ordinary length, so that it may be more easily accommodated inside the camera when closed. The inner wire of Antinous Releases will in future be coated with a deposit of copper to render it quite rust-proof. It may not be without interest to users of the release to note that the breaking strain of the wire is considerably over 112 lb.

Some New Christmas Mounts. Manufactured and sold by Messrs. Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

It may seem early to speak of Christmas mounts, but an excellent series for 1904 just submitted to us by Messrs. Marion speak not only too eloquently of the rapid passage of time and the proximity of autumn and winter again, but also of the enterprise of those firms who recognise the necessity of being first in the field with materials, etc., for the approaching busy season. We understand that consignments of these mounts are now speeding on their way to various foreign ports, but it is not only for export, however, that such early delivery is necessary. The view publishers at home who have to get ready their Christmas wares many months in advance are now securing Christmas mounts to suit the pictures and views they have had in preparation since the spring. The amateur photographer as well as the professional, it is needless to say, is also keenly alive to the utility of the Christmas mount, and uses no mean number. As the sizes in the collection we have seen range from the popular stamp midget to the cabinet size, with a vast choice in the matter of colour, motto, shape, and price, no amateur need be disappointed, whatever the size of his camera. For those who wish to avoid the trouble of pasting on their prints there is plenty of choice in the "slip-in" series. Perhaps the most notable feature in the 1904 collection is the series of folding cards, with view or seascape in colour on front page (facsimile of choice water-colour drawings by modern artists). The pictorial postcard is everywhere, and has been well provided for in this series. Naturally, those designed for this shape are all "slip-in" mounts. They are a means of transforming in a moment a "cheap"-looking article into a handsome Christmas card. The series we have seen contains no less than 235 patterns. This number, we venture to think, ought to supply something to suit the taste of everybody. A postcard to Messrs. Marion will procure full lists.

New Book.

"Advanced Hand-Camera Work," by Walter Kilbey. 96 p. Price 1s. Published by Dawbarn and Ward, 6, Farringdon Avenue, London, E.C.

This little volume deals in a practical manner with the ambitious efforts of the hand-camera worker, as distinguished from the mere snap-shotter. It concerns itself primarily with the work achieved by the focal-plane camera work—work that Mr. Kilbey made so particularly his own, and the information conveyed is in advance of that given by this author's previous work on "Hand-Camera Photography." The book is divided into five sections which treat exhaustively of types of shutter and apparatus, the practical work, plates and developers, and lastly, telephotography, stereoscopy, and orthochromatics applied to hand-camera work. The book is embellished with numerous illustrations in the text, while many excellent reproductions of Mr. Kilbey's high-speed work are printed on art paper, are also introduced. As a little book of reference on this popular subject, it should be in the hands of all photographers. Of particular interest to the amateur will be the chapter on plates and development of extremely short exposures. Under-exposure seems to be the bugbear of the focal-plane worker, and Mr. Kilbey's practical advice on the subject ought to be carefully read and digested. On the question of exposure the author writes himself remarkably clear, and the following short extract from the chapter on the subject will doubtless prove of interest to our readers: "One of the most difficult questions for one unaccustomed to high-speed shutter work is how fast he *must*, or how slow he *may*, work his shutter to get a sharp picture. Two speeds have to be taken into consideration, viz., angular velocity and actual velocity. The shutter will need to be driven three times as fast for a subject taken by the side on as would be allowed for the same subject if taken 'end-on.' That is, when coming towards, or receding from, the camera. The following formula is laid down in the text-books to assist the operator to find the correct exposure. Exposure in fractions of a second = Distance of object from camera in inches, speed in yards per hour, focus of lens in inches. For example, supposing the object is 50 yds. from the camera, and the focus of the lens is 6 inches, while the movement of the object is at the rate of 12 miles an hour, we get—

$$\begin{aligned} \text{Exposure} &= \frac{50 \text{ (feet)} \times 12 \text{ (reduce to inches)}}{12 \text{ (mils.)} \times 1,760 \text{ (yds. in a mile)} \times 6 \text{ (in. focus)}} \\ &= \frac{600}{126,720} = \frac{1}{211} \text{ (if a second about).} \end{aligned}$$

This is no doubt all very well in its way, but it always appears to me that, by the time one has worked out the answer, the subject will be miles away. I have therefore included the following table, which I would suggest be cut out and placed in some convenient place where it could be referred to at a moment's notice.—

	Right angles.	Towards Camera
Cycle racing, horses galloping...	1200	1000
Athletics, men running, &c. ...	600	300
Fast trotting	500	100
Driving	400	150
Pony and trap trotting	300	100
Yachts	200	100
Water polo and football	100	100

The table is made out for a 6 in. lens at 25 feet, a 7 in. at 29 ft., 8 in. at 34 feet, etc. A rule is, if you halve the distance, you divide the exposure by two; or if you double the distance, then double the length of the exposure."

News and Notes.

THE Academy of Science, Paris, has decided to award the Leconte Prize of 10,000 francs to M. Blondlot for his researches on the rays.

THE Braintree and Bocking Camera Club announces that their annual exhibition will take place on November 17 and 18. There will be open classes. Entry forms may be had from the Hon. Sec., H. Tilston, 81, High Street, Braintree, Essex.

WE have received a useful little booklet from Frank Gould and Co., advertising contractors, of 54, New Oxford Street, W.C., titled, "Some Notes on Advertising and Press Publicity." It contains some useful hints to advertisers, and a list of the principal London and provincial papers. A copy will be sent free of charge on application.

THE Rotherham Photographic Society's Fifteenth Annual Exhibition, to be held from October 19th to 22nd, will have six open classes, in which silver and bronze medals will be placed at the disposal of the judges. There are no entrance fees except in one class, and entry forms may now be obtained from the hon. sec., C. C. Hemmingway, Tooker Road, Rotherham. The judges will be Messrs. C. Barrow Keene and T. A. Scotton.

A PRINCESS Photographer.—Princess Christian and her daughter, Princess Victoria of Schleswig-Holstein, have left England for South Africa on board the "Walmer Castle." They have intimated their desire to visit the principal battlefields and the grave of Prince Christian Victor at Pretoria. Princess Victoria is taking her camera with her, though not the large collection of cameras and photographic material with which she is credited.

WIMBLEDON and District Camera Club.—The list of officers for 1905 has been sent us by the Hon. Sec. of this club. They are:—President, Peter Keary, Esq.; vice-presidents, W. Dowson, Esq.; S.C.C.; Gerald Craigie, Esq.; W. B. Marr, Esq. Committee: Messrs. Catcher (chairman), Russell, Magnus, Lyon, Knight, Packer, Reiner, and Wallis. Treasurer: E. Deacon, jun. Esq. Hon. Sec.: J. Munro, 96, Richmond Road, Wimbledon, S.W. Assistant Hon. Sec.: Miss Hatch, 71, Queen's Road, Wimbledon, S.W.

BIRMINGHAM Photographic Society.—On Tuesday, September 27, a conversational resume of "Some of my Experiences with Regard to Photography in Birmingham for the Last Half-Century—With References to Old Birmingham," illustrated by lantern slides, will be given by Mr. W. B. Osborn. Mr. Osborn was hon. secretary to the Birmingham Society of 1854. It is doubtful if any photographic society in the kingdom is possessed of a member with so long a membership.

No. 63 of "The Photo Miniature," just published, deals with a little-known phase of applied photography, i.e., "Photography in Advertising." The book contains many surprises, and, dealing as it does with the employment of photographic prints in the making of advertising designs and posters, opens up an almost untrodden field of activity that will doubtless be eagerly followed by many enterprising camerists in search of an outlet for their superfluous energy and talent.

THE Hull Society last Saturday paid their annual visit to Beverley Priory, and being favoured with a bright afternoon, much work was done in and around this fine old building. There appears to be always something fresh here for the camera and the enthusiastic worker. The attendance was excellent, and the stately columns, Percy shrine, statues, and choir stalls demanded the most attention: The outing proved most successful, which is very gratifying to the officers of the society, who have all along introduced so much enthusiasm into their excursions, and who look forward to good results and more all during the coming winter session.

SOME Distinguished Amateur Photographers.—The fact that the Queen has been busy with her camera at Cowes and secured an excellent snapshot of the King reminds one that there are many distinguished women in Society who are excellent amateur photographers, observes London Opinion. Her Majesty never exhibits any of her work, but lately some very good photographs taken by the Princess Victoria have been published. The Duchess of Bedford is another lady who

makes a hobby of photography, often spending a whole day in the park at Woburn Abbey, patiently waiting to get a good snapshot of some of her many pets. The Marchioness of Ormonde and her two beautiful daughters, Lady Beatrice Pole-Carew and Lady Constance Butler, are also well-known camera experts, and have several interesting studies of Irish peasantry taken at Kilkenny Castle.

HOVE Camera Club.—We learn that the Committee of this Association, acting on a resolution passed at their last annual general meeting, have acquired the first floor of No. 55, Western Road, Hove (over the shop occupied by Messrs. Sanders and Crowhurst) as permanent rooms for the club. The rooms were opened by the President (Alderman J. Colman, J.P.) on Thursday evening, August 25th. A lantern slide exhibition followed the opening ceremony. Now that this flourishing Southern society has acquired a home which it may regard with more satisfaction than its late periodic occupancy of rooms in the Hove Town Hall, we look to it to move with even more energy and distinction in the van of progress, as regards the furtherance of photographic activities in the South of England, than it had the opportunity of doing in the past.

THE ubiquitous photographer has more than once formed the subject of comment in the daily Press. The following incident, however, which has been reported in several recent morning papers as occurring at the siege of Port Arthur, deserves attention:—"Part of the Russian battalion advanced up the bed of the stream, and a number were shot as they emerged into the roadway. One wounded soldier had crawled back to the brook for water, and died with his face in the stream, and his canteen beside his hand, as though he had tried to fill it. In the road a young Japanese bent over a massive Slav with an arm under his head, holding a water-bottle to his lips. An enterprising photographer rushed up. 'Hold on there! Hold on there!' he shouted, enthusiastically, brandishing his tripod. 'That's just what I want.' He posed the wounded men more effectively, faced the Japanese about toward the camera, and hurried off for other pictures." "Brandishing his tripod," is good!

RESULT of the "Ensign" Film Competition for July.—This competition, we hear, has proved extremely successful. The first prize, £10, goes to Mr. William Elliott Brown, 1, Albany Street, Oban; and the second prize, £5, to Mr. J. Daly, 244, Brecknock Road, Tuffnell Park, N. The five consolation prizes of £1 each are awarded to Mr. W. Bulmer, 64, Musgrave Road, Bolton, Lancs.; Mr. W. Scott, 3, Montrose Terrace, High Street, Chard; Mr. Ernest Latter, 10, St. Mary's Street, Wallingford, Berks; Mrs. Walker, Grange Mount, Cloughton, Birkenhead; Mr. E. Staley, 115, Station Road, Burton-on-Trent. The consolation prizes were very closely contested, and Messrs. Bulmer and Scott only missed the second prize by one and three marks respectively. In connection with this competition Houghtons' Ltd., say they have had quite a lot of curious inquiries from would-be competitors, but the palm must be awarded to the lady who wrote ingenuously asking if they could send her the bottoms of any "Ensign" film boxes which were not required, as she wished to enter for the competition! The postage would be paid, she added. This is what comes of advising the competitors to "beg, borrow, or buy 'Ensign' film boxes."

THE Plymouth Exhibition, 1904.—The preparations for this exhibition, which will be held in the Drill Hall from November 2 to November 23 next, are already in a forward state. One of the leading features will be the photographic exhibition, the prospectus of which has already been issued. There are nine classes, including professional, amateur, open, and juvenile classes, and in each will be given as prizes gold, silver, and bronze medals and diplomas of merit, and a diploma of honour will be given for the best photograph in the exhibition. The judges are Messrs. Thomas Bedding, editor of the BRITISH JOURNAL OF PHOTOGRAPHY, and Walter D. Finch, head master of the Teignmouth School of Art. All entries must be made on or before Saturday, October 15, and exhibits must be delivered not later than Wednesday, October 26. The photographic section of the exhibition will be under the management of Mr. Chas. R. Rowe. The exhibition is under the patronage of the Earls of Morley, Mount Edgumbe, and St. Germans, Lords St. Levan and Auckland, the county and borough members for the Three Towns, the Mayors of Plymouth and Devonport, and the chairman of Stonehouse District Council, etc., Mr. Alfred D. Breeze again occupying the post of secretary and general

manager, the duties of which he discharged last year with such signal success.

"PRINTED in Prussia" are the significant words which appear on coloured picture postcards bearing reproduced photographic views of scenes not a hundred miles from Southport, says the "Liverpool Courier." The Prussians did not send over their camera men to obtain the views. The photographs were taken on behalf of the local publisher, who then cast about for the best and cheapest place for reproduction. As a result of his inquiries he had to seek help in Prussia, whence he obtained the pictures printed in artistic fashion at 18s. 6d. per thousand, while English art printers would not do the work for less than two guineas per thousand, or considerably over twice the Prussian price. What is indicated by these facts—and they are facts and not merely figments of the imagination? Britons are continually being invited to take their cue from the Germans, who are said to be at the top of the educational tree; while in other respects they are setting examples to John Bull, who used to consider himself a very superior person. Do the low prices above quoted indicate that the Prussians are superior to the British? Or do they give evidence of long working hours and lower wages among the Kaiser's subjects? There must be some explanation as to how the Prussians can supply at 18s. 6d. per thousand pictorial postcards which the British cannot produce for less than £2 2s. per thousand.

WAR Cinematography.—With the up-to-date war correspondent the camera may be said to have superseded the pen. Mr. G. H. Rogers, who has just returned from Manchuria, carried the equipment of the war correspondent a stage further by accompanying the Russian army with a cinematograph machine, and he has brought back with him to England some exceedingly interesting films. His most remarkable experience was cinematographing an execution of Hunhuses by the Chinese authorities at Mukden. (The Hunhuses, or Chunchuses, are Chinese brigands, mainly Manchurians.) To a representative of the "Daily Chronicle" Mr. Rogers recounted some of his experiences, and showed him the war pictures. "These films," said Mr. Rogers, "were not taken for exhibition in public; but as I had the opportunity, I thought I would take it. I can assure you it was an experience I never wish to have again. The execution itself is not the worst thing in China; it is the preliminaries that would correspond to our police court proceedings that are so terrible. According to the Chinese law, no criminal can be executed until he has confessed his crime. If the prisoner will not acquiesce in the sentence, they take steps to make him by applying torture, and it is beyond the Western mind to comprehend the appalling details of cruelty that the Chinese nature can sink to."

Patent News.

The following applications for patents were made between August 8 and August 15, 1904.

Developing Apparatus. No. 17,244. "Improvements in photographic developing apparatus." James Wyndham Meek.

Cameras. No. 17,367. "Improvements in or connected with photographic cameras." (Emil Becker and Otto Palmer, Germany) Eugen Emck.

Cameras.—No. 17,408. "Improvements in or relating to photographic cameras." Houghton's, Limited, William Albert Edwards and Herbert Holmes.

Pigment Processes.—No. 17,610. "Improvements relating to pigment photographic processes." Complete specification. Hans Schmidt.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
30	Nelson Photographic Society.....	Gum Bichromate Process. Mr. T. Hudson.
Sept.		
1	Hull Photographic Society	General Meeting.
2	Watford Photographic Society	Informal Meeting.

Correspondence.

- Correspondents should never write on both sides of the paper, notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

THE PHOTOGRAPHIC LABOUR MARKET.

To the Editors.

Gentlemen,—Like "Hornsey," I also have been interested in reading the various articles on the above, and your concluding note to Hornsey seems to me to hit the right nail on the head; the case can be summed up in that one word "inability." There are places waiting for men who are "highly skilled photographers."

To use a simile, there are fence-menders who call themselves carpenters, and there are carpenters who can fit up a mansion; the former may want a job, although they may call themselves "highly skilled"; the latter never want a job, because they are skilled. "highly skilled photographer" is not made out of any stuff, brain being as necessary as in any other business, in spite of "rapid development plates," and the various "push the button" appliances. It is difficult to appreciate what "highly skilled" means, without a thorough knowledge of the routine of the best houses, which necessitates experience therein. The man who learns his business in a slipshod fashion or picks it up anyhow (with a guinea hand-camera it may be) is at a terrible discount, and can soon be read by the experienced employer. I say experienced advisedly, because some employers have never learned the business themselves, and consequently take a man very much at his own estimation. These are the men, doubtless, who think they get a hundred applications from "highly skilled photographers" for one situation. These conclusions are forced upon me by thirty years' experience in the best portrait and commercial houses.—Yours truly,

August 17, 1904.

OVER FORTY (but not too old).

THE R.P.S. EXHIBITION.

To the Editors

Gentlemen,—I shall be glad if you will remind your readers that exhibits for the Royal Photographic Society's Exhibition sent by carrier must be delivered at the New Gallery, 121, Regent Street on or before Thursday, September 8, and those delivered by hand unpacked on Friday, September 9. —Yours faithfully,

A. W. W. BARTLETT.

66, Russell Square, London, W.C.,
August 20, 1904.

Secretary.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen.—In view of the light which has been recently thrown upon this subject by the discovery of "N" rays by Dr. Blondelo of Nancy, which, by the way, are probably identical with the "Odic" rays of Baron von Reichenback, discovered by him many years ago, no doubt photographers will modify their views regarding the possibility or otherwise of obtaining photographs without the aid of visible light.

As bearing on this subject, I enclose "cutting" dealing with the experiments of Professor Goodspeed, of the University of Pennsylvania, which, as it fully explains his method of working, should be most useful to those who are exploring this new branch of photography. If X-rays are not available, I would suggest the substitution of radium or the rays of the sun.—I am, yours, etc.,

R. STEWART.

Melbourne. July 12th, 1904.

[The cutting referred to is reprinted on p. 752.—Eds., "B.J.P."]

To the Editors.

Gentlemen,—As very little appears to be known about this subject, take the liberty of offering a few remarks. Psychic photography is

of which there are many, of psychic phenomena, for particulars which I refer you to the writings of Sir O. Lodge, Professor Crookes, Sir W. Crookes, Camille Flammarion, and others.

The medium is simply an instrument in the hands of spirits (I use the word as it conveys what is generally understood). Of their method of working nothing is known. All that is known is that certain electrical conditions of the atmosphere are unfavourable; so also is the presence of persons of strong will, and who are antagonistic to the medium. Will power directed against the medium produces much the same effect as does the will power of the hypnotist on his subject.

Notice that some of your correspondents are puzzled over the double lighting of some of the photographs, and seem to think it is a proof of fraud, but it is reasonable to suppose that any photographer would cause suspicion by double lighting when it is quite as easy to light from one direction only? As a matter of fact, light, as it is commonly known, plays no part in the production of these pictures, and is only necessary for the lighting of the material. The psychic photograph is made direct on to the plate, and consequently the camera and lens are unnecessary, a dark slide being convenient. I have recently noticed that many of the photographs are undoubtedly crude mental impressions, and the question whether all are not so.

As far as the only theory that fits in with my experience is the dualistic one, and I shall have to hold on to it until a better is found.

The great difficulty that lies in the way of investigators is the uncertainty of getting results, and this applies not only to spirit photography but also to all the other phases of psychic phenomena. I think this will remain with us until our scientists have mastered higher laws which are falsely named supernatural. In my own case I have not for many months past been able to get any results, and on two occasions have I been successful when sitting with friends. Mr. Blackwell to accept Mr. Henderson's challenge, under the conditions named, would be to court certain failure. The scientist is a man to investigate (it is a scientific subject) and not those who are not competent. On this subject Mr. Henderson hints that your late friend, Mr. Taylor, changed his views shortly before he died; but is it surprising with death staring him in the face and his physical, and especially his mental, faculties failing him?—I am, yours, etc., X.

The correspondence on this subject was definitely closed many months ago, so that the insertion of the above letters, one from a considerable distance, and the other from a gentleman who had no opportunity of joining in at the time, must not be taken to indicate, in any part, any desire to have the matter further discussed in these columns at present.—Eds. B.J.P.]

Mr. PERCY PHILLIPS, a war correspondent sent out by the "Daily News," who has recently returned from the seat of war, has brought back about 900 films taken with the No. 3a folding pocket Kodak. All of these were developed in the Kodak daylight development machine, and some sixty-five reproductions from these negatives have already appeared in the "Illustrated London News." Prints are now being made from the rest of the negatives by Kodak, Limited, and a fine collection of reproductions of the stirring scenes of the war of the few months will result from them.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted subject to the usual conditions, expressed or implied, as to what appears in the portion of the paper.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- M. H. Grocock, 1, Ainslie Street, Ulverston. Photograph of Fan Bellows.
J. E. Reeves, 48 and 50, Hermit Road, Canning Town, London. Photograph of West Ham United Football Team, 1904-1905.
F. Deakin, 121, Snargate Street, Dover. Photograph of J. A. Weidman.
J. Mack, Alexander Terrace, Coleraine, North Ireland. Two Photographs of Visitation of Hon. Irish Society to Coleraine.
J. G. Charlton, 14, Mercery Lane, Canterbury. Photograph of Central Tower of Canterbury Cathedral with scaffolding.
R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. Photograph of Stockton Cricke Team, First Eleven.

HENRY LEACH.—If you refer to the advertisement columns you will see that Messrs. Wellington and Ward and the Rotary Photographic Co. also make a non-curling film.

"WILKINS."—Your question is not quite clear, but we presume you wish to know what we consider a reasonable remuneration in the circumstances: anything between £3 3s. 0d. and £8 8s. 0d. per week for a business of the nature indicated.

SEPIA ENLARGEMENTS.—KARL KLIEMECK says: "I should be greatly obliged if you can give me a good formula for sepia enlargements. I am using bromide paper and metol-hydroquinone developer." In reply: We refer our correspondent to our reply to "Salisbury," p. 760. The method for obtaining sepia tones in the Hypo-Alum bath there given is quite reliable.

COLOURS FOR PHOTOGRAPHS.—MABEL asks: "Could you tell me if there are any special kind of colours used for tinting small photos like the one enclosed, or if they require to be prepared before?" In reply: Transparent colours for the purpose are supplied by all the large stock dealers, such as Houghtons, Fallowfields, Marions, or Butchers.

COPYRIGHT.—G. P. asks: "(1) Can a foreign artist obtain registration of copyright of his work in England. (2) If so, and supposing the copyright is assigned to a firm of English publishers, does this copyright expire seven years after the artist's death, or when? In reply: (1) Yes. (2) The copyright endures during the life of the author and for seven years after his death.

PINHOLES.—REGULAR READER asks: "Can you kindly give me any advice on the following: I have developed a quantity of negatives (which have been good) and during the drying they have got a number of pinholes in the film?" In reply: If there are holes in the film the only thing that seems to us to be done is to spot them out in the negatives.

FAULTY PRINTS.—P. C. AND SON ask: "Can you tell me what is wrong with enclosed print; in two days I have had all my work destroyed and cannot account for it?" In reply: As no particulars whatever are given it is impossible to say by merely looking at a print from what cause the trouble proceeds. Probably the toning solution was out of order. Correspondents are not replied to by post.

BOOKS WANTED.—T. C. GODDARD says: "Would you kindly send me a list of good books on retouching, posing, lighting, developing of plates, and other books on photography?" In reply: A list of the books desired would take up more space than is at our disposal in this column. Therefore we refer our correspondent to pp. 974-6 of the "Almanac." He will

there find a list of the principal text books relating to photography. We do not reply to correspondents by post.

REDUCER WANTED.—J. C. WINDRUM asks: "Will you, please, give me a formula for a cheap reducer for negatives, one solution, which will keep indefinitely and may be used and returned to the bottle?" In reply: Belitzski's is the most satisfactory; it will keep indefinitely in the dark, and can be repeatedly used:—Potassium ferric oxalate, 20 grs.; sodium sulphite, 200 grs.; water, 5 ozs. Dissolve and add oxalic acid (crystals), 75 grs. When the solution is a deep green, pour off from any undissolved acid, and add hypo, 2½ ozs.; water to 10 ozs.

BLACK AND WHITE TONES ON ARISTO S.-T. PAPER.—"H." asks for a formula for a toning bath which will give black and white effects on Aristo S.-T. paper. In reply: We suggest the following bath as likely to give what you require:—A. Gold chloride, 1 gr.; sodium acetate, 30 grs.; water, 40 ozs. B. Potass. chloroplatinite, 1 gr.; phosphoric acid, 2½ oz.; water, 40 ozs. Tone in A. until prints are purple; wash well and complete toning in B. Then fix and wash as usual. (2). There is no paper on the market with all the qualifications you mention.

PHOTOGRAPHY ABROAD.—J. B. says: "I am anxious to know if there is much of an opening for photographers abroad. I am an amateur and am anxious to go abroad and study under some firm and eventually start on my own. Could you give me an idea of the best place to go to and how I could communicate with a likely firm at that place?" In reply: We know of no place abroad that is not at the present time well supplied with photographers. We should think your best way would be to advertise your wants in the photographic journals of the country you have a preference for.

STAND DEVELOPMENT.—T. W. BARRIE asks: "Will you kindly give me a formula for making a reliable developer for stand development for a number of plates—one that can also be used at times to develop single plates in the ordinary way, and for bromide papers?" In reply: Any developer that will keep well can be used for stand development if diluted. The following should answer your purpose:—Metol, 16 grs.; hydroquinone, 24 grs.; soda sulphite, 200 grs.; pot. bromide, 2 grs.; pot. carbonate, 400 grs.; water, 10 ozs. For use as stand developer dilute 1 part of above with 60 parts of water. For bromide papers dilute with equal quantity of water, or for ordinary development use as given.

QUICK PROOFS FROM WET NEGATIVES.—N. D. ACKERSON says: "I have been told it is possible to obtain prints from the wet negative as soon as developed. I shall be glad if you can inform me of this method." In reply: With a little ordinary care this can be easily done without in any way injuring the plate. After fixing, the negative is submitted to a slight washing for a few minutes under a tap. While this is in progress a piece of bromide paper is soaked in water, face down, in the dark room, of course. The wet negative can now be slipped under the paper as it lies in the bath flat and limp, and, avoiding air bubbles, they are removed and any water on the glass-side of the plate wiped off. Exposure can now be made by either holding the negative and paper before an ordinary artificial illuminant, or standing the same on a drying rack. The bromide is then developed in the ordinary way, and the negative receives its complete washing.

COPYRIGHT, GELATINE.—IGNORANT asks: "(1) Will you kindly let me know if it be possible to copyright photographs of some old prints of this town? A friend has offered me some for postcards but am afraid, as they are very many years old, they will be copied and reproduced as blocks if not registered? (2) Can you also give me a preservative for gelatine, such as would be used for chrysotelem, one that would not hurt albumenized paper; I want to mount photos on glass for colouring with transparent colours at back; I thought boracic acid but am afraid to use it without your opinion, which I should esteem greatly; if that would do, will you say what quantity boracic to the ounce of solid gelatine?" In reply: (1) If you make your reproductions copyright it will be illegal for anyone to copy them. But it will not prevent anyone from copying the original prints. (2) We should prefer to use carbolic acid,

say, one or two drops to each ounce of the solution, with that we should recommend the solution to be used a day or two of its preparation.

BLACKENING BRASS.—J. M. C. B. asks for a formula for blackening some brass-work that he is fixing to a home-made camera. In reply: The following procedure will answer this purpose. Dissolve copper wire in strong nitric acid until no more dissolves. The brass to be blackened is then made fairly hot in a Bunsen flame or spirit lamp, and is then plunged into the solution, after which it is reheated in Bunsen flame until it turns black. Or, as another worker gives it:—Nitric acid, 4 oz.; copper wire, ¼ oz. When dissolved, add ¼ oz. of water. The object must be first cleaned, then heated and immersed in the mixture. Take out, and brush all the green off until the article goes black. Can be polished with a blacklead. Another method:—Take 2 grs. of lampblack, place it on a slab, and grind it down to a smooth paste with the addition of two or three drops of gold size. When rubbed up quite smooth, add 10 drops of turpentine. Apply it at once, thinly, with a camel's-hair brush in the work. Hang up by a wire. And yet another:—Make a solution of 1 part of carbon dioxide ammonia in 20 parts of liquid ammonia. Suspend the brass to be blackened, which must have been previously polished, in the mixture, and leave it until it has become perfectly black. Remove and dry. This latter will bear polishing.

DRYING POSTCARDS FLAT, ETC.—"MANAGER" says: "I turn out a great many bromide postcards, but at quite a loss to keep them flat, as they have a great tendency to curl up. Will you kindly answer the following questions:—(1) Is there any remedy to prevent curling? (2) Can you recommend a work on the manufacture of bromide paper, and (3) a book on bromide printing?" In reply: (1) The following has been recommended for making postcards dry flat:—pieces of wood are tacked on a piece of board four inches square (preferably putting a sheet of blotting paper under, so that it absorbs the water that drains from the postcards). When the postcards are washed, take them out of the final water, place them one by one between the two pieces of wood, in a curved way, film upwards. Allow them to stay so until thoroughly dry, then take them off, when they will after a while flatten themselves. If they are wanted quickly, then under some weight, say between two books. (2) Dr. Eder's "Handbuch der Photographie," Abney's "Photography with Emulsions," and "A Treatise on Photography," are all good. (3) Just's "Bromide Paper." (3) The foregoing works, and Lambert's "Bromide Printing," "Photo Miniature No. 16," and "Practical Photographer, New Series, No. 1," and all the books of general photography.

HYPOTONING-BATH FOR BROMIDES.—"SALISBURY" says: "I find a formula for bromide prints with hypo and alum. All the instructions I have carefully carried out, but I have not succeeded in getting any other but the ordinary black tone. As I have seen obtained with a similar formula, there is obviously something wrong with my mode of working." In reply: When the alum bath is to be employed, the print, after development, should be thoroughly fixed in the ordinary hypo bath composed of 4 ozs. hypo in 20 ozs. of water. It should then be transferred to an alum bath (saturated solution) for ten minutes, and well rinsed and dried. When dry it is ready for toning in a hypo-alum hot bath, which should be made as follows:—Sulphuric acid, 10 ozs.; alum, 1 oz.; boiling water, 7 ozs. Dissolve the hypo in the water first, then add the alum. When all is dissolved the solution should be milk white. This solution should not be filtered, and it works better as it comes a little old; it may be strengthened from time to time with a little fresh solution. Never throw the bath away entirely, but replenish it in the manner stated. The results are obtained by keeping the bath hot, or as warm as an emulsion will stand, say 100deg to 120deg. Fabr. In the prints will tone in thirty to forty minutes. A new bath should be used to reduce the prints rather more than old. When the prints may be placed in a tepid solution of water, 70 deg. Fahr., alum, 2 ozs. Then wash thoroughly.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose continuing the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable features of an informative nature will be added.

IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that this year's entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1—next—a fortnight earlier than usual, so as to be well advanced of the Christmas publication season.

EX CATHEDRA.

Nature Lectures.

We have been glad to receive from Mr. F. Martin Duncan, the well-known natural history photographer, the syllabus of a series of nature lectures, which he proposes to deliver during the coming autumn and winter months. The photographic illustrations are both cinematograph and lantern slides; and the subjects treated of are "Pond Life," "Denizens of the Deep," "Devil Fish and Kraken," "Flesh-feeding Plants," and "With Microscope and Camera." Thus the lecturer's repertoire covers a wide and fascinating field. Mr. Duncan, whose address is 39, Bradley Gardens, West Ealing, London, W., has justly earned great renown for the interesting manner in which he lectures on popular science themes, and as the accompanying photographs exhibit a very high degree of technical skill indeed, the executives of photographic, literary, or other societies that engage Mr. Duncan's services may rely upon having a unique and instructive evening's entertainment.

The Genesis of "Punch."

A very interesting booklet has recently come under our notice. Its title page bears the inscription, "Mr. Punch; his Origin and Career," with a facsimile of his original prospectus in the handwriting of Mark Lemon. It bears no date, but there is internal evidence that it was published in 1870, when "Punch" was thirty years old. Its retrospect of these thirty years contains a reference to photography, but it would have needed a prophetic eye to note how useful the camera would some day be in preparing pictures for the "London Charivari." "Photography," we read, "was still in its infancy, and was generally called daguerreotype. Cartes de visite were entirely unknown; the features of your friends were shadowed upon a metallic surface, and you had to coquette with them a great deal in the light before they would let you see them, and even then only in a slanting kind of way." This, we think, is an admirable description of a daguerreotype portrait, and those who own such things know well how they have to "coquette with them" at all angles before the particular one which is right comes along. But beyond this reference to the early days of camera work, there are many things in this book which will repay perusal, and notably one with regard to the conception of the "Illustrated London News"—the first of our pictorial journals—if we omit consideration of the spasmodic attempts at producing journalistic pictures which preceded its appearance. "Punch" was born at No. 3, Crane Court, Fleet Street, at the printing office of Mr. J. W. Last. In the same house there was carried on the business of "Parr's Life Pills," by Mr. Herbert Ingram. Mr. Last was one of the earliest promoters of cheap illustrated literature, and also one of the first to execute the finer kinds of printing with a cylinder machine. This

machine was successfully applied to the production of "Punch," and this, it is suggested, gave Mr. Ingram the suggestion of "The Illustrated London News." In this way "Punch" led the way for the more serious periodicals, and a quack medicine—if we may say so without offence—was the means of finding the sinews of war for one of the most successful newspaper speculations ever undertaken. Those who have not followed the history of "Punch" would be perhaps surprised to learn how many eminent writers and artists have been associated with it since it first saw the light. Among the former we note the names of Douglas Jerrold, Tom Hood (his famous "Song of the Shirt" first appeared in "Punch"), Tom Taylor, Thackeray, and Tennyson. And among the artists were, besides the well-known names of Leech, Chas. Keene, and Du Maurier, those of Birket Foster, and John Gilbert. The artists and writers for the merry periodical seem to have been always a rather exclusive set, jealous of the intrusion of outsiders. Of course, outsiders have always been anxious to get into the charmed circle, and the contributions they send in are as remarkable for their number as for their generally feeble character. But an exception was found in one missive which came to "Punch" anonymously, the author of which, at least up to the time of the publication of this brochure, remained unknown. This was the famous "Advice to Those About to Marry—Don't." We may suppose that this dictum has been more quoted than any other of the same age, and its value to "Punch" as an advertisement which cost it nothing, must have been enormous.

* * *

Art Critics.

The season for the autumn exhibitions is again approaching, and we look forward as usual to the critiques which appear so regularly in the minor journals. Generally written by those who know little about photography and less about art. It seems to be forgotten that criticism is an art in itself, which requires training before it can be exercised with any good result to anybody. How many of the young ladies and young gentlemen whom we see busily marking their catalogues on press days at the picture galleries have had this training? Very few, we think. We would advise them while it is yet time, and before they essay to spill any more ink, to look up Ruskin's notes of the principal pictures of the Royal Academy and other exhibitions, which were published between the years 1855 and 1859. Ruskin devoted his life to the study of Art, and was a highly competent critic, knowing how to praise a work of merit, and how to condemn one in no measured terms when it deserved censure. These notes are not only valuable to the aspiring art critic, but are most interesting to all lovers of pictures because of their candour, and their references to works which have lived. There is no beating about the bush whatever may be the reputation of the artist under consideration. Here, for instance, is a good rap over the knuckles for Maclise: "Mr. Maclise is supposed to draw well and realise minute features accurately. Now, the fact is, that this work has every fault usually attributed to the pre-Raphaelites, without one of their excellencies. The details are all so sharp and hard that the patterns of the dresses force the eye away from the faces, and the leaves on the boughs call to us to count them. But not only are they all drawn distinctly, they are all drawn wrong." Then, alluding to a landscape by no less a painter than T. Creswick, he writes: "Nothing is really done. The cows have imperfect horns and hides; the trees have imperfect leaves; the sky imperfect clouds; the water imperfect waves. The colour, of a heavy yellow with dun green, is worse than imperfect." Of one of Frith's pictures he notes that "It is not a kind of painting which will ever bring great fame, or deserve it; but it is better than spurious

'high art.'" The next extract which we select from the criticisms is a gem which reminds us of some of the things which have lately been said of the Royal Academy in connection with the Chantry Bequest report. Ruskin referring to a picture by David Roberts, and he suggests that if he had "painted more, instead of less from Nature he might by this time have been a serviceable painter. Is it too late to warn him that he is fast becoming nothing more than an Academician?" One more quotation we will make, and it is worth noting, for the words apply equally well to a photograph as they do to a painting or drawing. Referring to some studies of Nature, Ruskin says of them that they are "Very good in their way; rather things to be kept in the artists' folios, for their use, than to be exhibited." Some may think that a few of these trenchant remarks are unkind, and must have given pain to those whose works are so mercilessly criticised, but even at the risk of giving offence to those who cannot bear reproof, is it not well that that reproof should be administered when it is deserved? All photographers who have given any consideration to the subject know well that there are many whose works are hung upon the walls of photographic exhibitions who would have benefited more by a little timely castigation instead of the adulation which they have received from irresponsible and ignorant critics. If Maclise, Creswick, Frith, and other well-known artists deserved censure, what do some of our perpetrators of exhibited monstrosities not deserve?

* * *

Municipal Photographs.

London has long had the reputation of being one of the healthiest places in the world, and those unfortunate enough to be unable to spend an autumn holiday comfort themselves with the reflection that if they lack the benefit of fresh air the atmosphere of the big village is not to be despised. But according to recent reports from the Medical Officers of Health for the larger area called "Greater London," there is vast room for improvement all round. These gentlemen are ever on the watch for the weak places of our municipal administration where disease is likely to obtain a foothold, and we all of us owe more to their persistent care than we are apt to give them credit for. One Medical Officer, who has the health of Battersea under his care, has made a startling innovation of illustrating his report with a photograph. This course we hope will be followed by other officers, for there is no gainsaying the fact that a health report, be it of the most painstaking and authoritative kind, is rather dry reading, and is apt to be passed over by the many and pigeon-holed by the few. But if it is illustrated by pictures, pictures which are true to life and which make the citizens acquainted with the realities of existence as experienced by their poorer neighbours, it will not be ignored, or thrown away. People want to know what the pictures mean, and will refer to the text and perhaps come to see how much they are, or are not, interested in the condition of things described. The picture in this instance represents an underground bakehouse. We were under the delusion that these maddening dungeons for preparing the staff of life were things of the past, but it seems that we were wrong. Here is the photograph, and its evidence is indisputable. One photograph, taken in one out of the twenty-eight boroughs into which London is divided, is not much. But it is a pioneer picture which we trust, by the time that the next report is issued, will have many followers. And there is a wide field for photography here. There are, for example, the underground kitchens of the restaurants which for some unexplained reason are not placed on the same footing as the bakehouses. There has long been a suspicion that some of our gorgeously-appointed diners

es have kitchens which it would not be desirable for diners to see. We want photographs of these places in order to know what they are like. One of the reports speaks of a sausage shop where the meat is chopped in a cellar in which a horse was stabled. The horse's duty is to turn the chopping machine, and the only way he can be got out of his underground prison is up "an incline plane down from the shop floor." We need not hazard a guess as to what becomes of the poor animal when his life's work is done, but it would be interesting to see a photograph of that cellar. Then there are the ice cream parlours of the Italian quarter, which would need a lens of the shortest focus. Other pictures are wanted to throw light upon the inner working of London's huge milk industry. According to one Medical Officer the deaths in London are caused from the use of unclean and polluted milk number many thousands "annually. It is here that photomicrographs would usefully supplement ordinary camera pictures. It is an astonishing thing that in spite of sanitary laws, and laws against adulteration, the things reported by these medical gentlemen should be allowed to go on almost unchecked. If photography can help, as we believe it can, in ventilating evils fraught with such danger to the community, it has surely never been applied to a better purpose.

"MORE Light for the Dark Room" is the title of a handbook dealing with the "Geka" Flexoid filters, prepared by Dr. G. Krebs, Offenbach-on-Main, for which Messrs. A. E. Staley and Co., of Davies Inn, London, E.C., are the agents. The filters, which have a flexible support, are designed for dark room and orthochromatic exposures, and are made according to formulae supplied by Dr. Miethe. Messrs. Staley and Co. will send a copy of the handbook free on application.

THE Royal Academy intends at an early date to revive the degree "Associate Engraver," writes the Art Critic of the "Morning Post," to which no one has been elected for many years. The possibility of such a revival was hinted at in this column some months ago, when a prominent landscape painter Academician took the first step in the matter by proposing that the Royal Academy should elect one Associate Engraver. The Royal Academy regarded the proposal with favour, so much so indeed that it has been agreed that two Associate Engravers shall be elected, and it is probable that one at least of the elections will take place early in 1905. Of the old Associate Engravers of the Royal Academy only one survives, and he has long been on the retired list. This is Mr. Frederic Stacpoole, R.A., an artist who in his time engraved many well-known pictures, among them Mr. Holman Hunt's "Shadow of the Cross," Mr. J. M. W. Turner's "Rain, Steam, and Great Bridge," and Lady Butler's "Calling the Roll after the Engagement, Crimea." The elections should be interesting, but it is idle to speculate on the probable identity of the new Associates without some idea of the way in which the Royal Academy proposes to interpret the term "engraver." Of late years a new school of etching engravers has sprung up, and from the ranks of these—among whom are included men of much ability—the Royal Academy may make its selections exclusively. On the other hand, the Royal Academy may take a broader view of the term "engraver," and confer one of their associateships on an etcher, a step that would be welcomed by the majority of artists. Of course, the Royal Academy already contains several etchers of eminence, but these artists were elected solely on their qualifications as painters. Though there seems to be a chance that the etcher may receive Academic recognition, the artist in black and white remains as far off as ever from the A.R.A. Charles Keene's name was long on the list of candidates for associateship, and so was that of Du Maurier, but it is doubtful whether either ever received a single vote. Phil May's name was never placed on the list, but on it may be found those of several of the eminent black and white artists of to-day. Among these candidates are the veteran Sir John Tenniel, Mr. Linley Sambourne, Mr. William Small, Sir William Rothenstein, Mr. Maurice Greiffenhagen, and Mr. Caton Woodville, but, except as a painter, none of them is regarded as having a chance of election.

OFFICIAL RECOGNITION OF PHOTOGRAPHY.

INITIATED abroad, the post-card mania has at last taken firm root in our conservative old country, and now constitutes an enormous industry. Although a certain proportion of these popular picture cards are from drawings, the major part are photographs pure and simple, and many know to their cost the way in which this cheaper form of print has killed the trade in ordinary views.

It is in holiday times that the sale of post-cards reaches its maximum. At Douglas, Isle of Man, it is said that in the course of a single day last season the output was over one hundred thousand. At Llandudno the same number passed through the post-office weekly, while at Ilfracombe one firm alone sold a thousand cards per day. Blackpool is credited with sending away ten thousand cards in a month, and doubtless other holiday resorts could boast of a similar trade in cards; for a rough general estimate gives 25 per cent. as being the amount which pictorial post-cards bears to the letters in the average outgoing mail.

Hitherto this huge trade in post-cards has been confined to private enterprise, but now an important change is foreshadowed. The official mind has grasped the idea that the illustrated post-card may be turned to good account, and the Postmaster-General of the Australian Commonwealth must be credited with being the first to realise its utility. It must not be thought that the Government is bent upon entering into competition with the private trader with a view to benefiting the revenue, for this is not the case. The idea is that by the issue of sets of post-cards, each set representative of one particular State, the cause of emigration may be greatly furthered. One State will be able to advertise its scenic glories, another its pastoral advantages, another will show its gold mines, doubtless with huge nuggets lying about ready for the expectant stranger to grasp; still another will show its sugar plantations, and so on. With this end in view the Postmaster-General is inviting competitive designs, and will offer first, second, and third prizes for the best pictures sent in from each State. There seems to be no restriction as to the sort of pictures desired, so that artists in oil, water, or crayon, as well as photographers, will be all entering into rivalry with one another in their endeavour to carry off the rewards.

This idea of picturing a country or district in order to entice visitors to its hospitality is an old one, but it has not been carried out before in such an effective manner. It has been done by posters, by pictures in guide books, in railway carriages, and by way of illustrations for inspired articles in various journals. But all such methods point to a limited circulation. With the post-card it is different, for such pictures are, as a rule, not destroyed; some people, indeed, collect them, just as they collect postage stamps, and hoard them as if they were gems; and there is a method in such madness, for certain stamps will to-day fetch far more than their weight in the most precious of precious stones. It is doubtful if any pictorial post-card will ever command a fancy price, but it is certain that one of good design will have an enormous circulation.

And there is no kind of doubt that a picture will appeal to the ordinary man and woman as no written description will. In spite of three decades of Board School education we have constant evidence that a very large class in this country never troubles itself with any literature at all. It vegetates. To this class from which a large number of emigrants is drawn, a picture is attractive, something which they can understand at a glance. And, of course, the pictures are all of the most roseate hue. To look at some of the illustrations, say in one of

the emigration handbooks issued by the Great Dominion of Canada, one would think that that country was a kind of Garden of Eden, where the sun was ever shining, and where there was no such thing as 40 deg. below zero—a land flowing with milk, honey, and all sorts of other good things, where a farm of 160 acres can be had almost for the asking. Of course, the Canadians will at once take on the post-card notion, and repeat these smiling pictures in that convenient form.

And it is not only Canada and Australia which will start these travelling picture galleries. We shall not be surprised if, before many months have passed, all our other colonies advocate their claims to notice in the same way. The stamp-collecting mania has been the means of spreading a knowledge of geography which no books have ever done so effectually, and probably the pictorial post-card is destined to do more in this way even than the stamp. We can, in fact, almost look forward to the time when books about our colonies will not be needed at all, and when all knowledge will be disseminated through the medium of the post-office in union with the camera.

But there is another kind of official publication which, in one instance, is illustrated by photographs. It is a blue-book which has just been issued by Messrs. Eyre and Spottiswoods entitled, "General Descriptive Report on the Bahama Islands, in which is included the annual report for 1902." It is admitted on all hands that yellow-backed novels find far more readers than do the blue-books issued under Government direction. Of course, this state of things is very sad, for while the blue-books deal with matters of more or less vital importance to the community at large, and comprises pages of statistics relating to the expenditure of public money, the yellow-backed volumes contain ephemeral fiction which can only appeal to the frivolous mind. The compilers of these cerulean official documents have evidently long seen that they have many rival publications to compete with, and they have at length hit upon a method of securing attention from the multitude. They have followed the lead of certain of our cheapest journals, and have enclosed between the two covers of the Bahamas Report a quantity of photographs; yes, real half-tone blocks printed upon good surfaced paper in order to give them every chance of appearing effectively in printing ink.

In case any of our readers should so far forget their school exercises as to be unable to call to mind at once what the Bahamas are, we may mention that they are a group of islands belonging to Britain on the coast of North America. They are of particular interest as representing the land first discovered by Columbus in his voyage to the New World.

The photographs appear to be quite subsidiary to the general purpose of the blue-book, and are placed at the end of the volume as pictorial addenda. They are thirty-two in number and comprise views of Government House, pictures illustrative of the sponge fishery—which is the most important industry in the Islands—and various views illustrative of the general scenery. Quite half of them seem to have been taken with some form of panoramic camera, for their measurement is 11 by 3 inches. They are of fair quality and, of course, give a much better idea of the Bahamas than any written description could afford. With such a hopeful beginning we may look forward to the time when other blue-books will be illustrated in this manner.

It is true that many of these official volumes deal with subjects of such a nature that pictorial illustration would be impossible. A photographer would find it difficult, for example, to illustrate a report on the metric system.

But what zest would be given to the blue-books relating, say, to the war in the Transvaal if they had been illustrated by photography. At present people are deterred from consulting these authoritative volumes in their desire of being bored by ponderous statistics and uninteresting details, and they will argue about matters which they do not understand until they are black in the face, when all the time these blue-books, which contain very information that is wanted, lie unconsulted upon the shelves of the public library. When the volumes could be illustrated, like this one upon the Bahamas, they would be considered interesting enough to assume the status of works of reference, and will become as dog-eared and thumb-marked as the postal directory of the same establishment. So we welcome the pictorial blue-book both in its own sake, and because it finds fresh employment for the photographer.

STORING NEGATIVES.

DISCUSSING, with a well-known member of the profession the question of the various modes of storing negatives adopted by professional photographers, we were not a little surprised to hear him say that he did not think that the storage, at any rate of portrait negatives, was worth the trouble and expense involved, the public taste being so capricious that negatives were, save those of public characters, rarely needed for replicas, except in the case of a death, and that it was a poor game to keep thousands of negatives on the chance of some one or two of the originals dying within the next dozen years, and their friends ordering half a dozen copies. This view, of course, could only be founded on personal experience, and to formulate a general rule from a particular instance would in the present case be rather illogical and unwisely. Further, it is obvious that, even granting the existence of a capricious public, the demand, or the absence of demand, for repetitions must be largely influenced by the character of the clientèle. A business which relies mainly on chance sitters does not require anything to be given to the storage question, while, contrariwise, one made up entirely by connection may find the gradually increasing store of negatives to be a very valuable property.

Speaking generally, however, there seems to be a consensus of opinion that the business of the portrait photographer has gradually been undergoing a radical change. Since the time when the production of a negative, from being an operation of some moment, became an affair of mechanical simplicity—as the production of the dry-plate has caused it to be. A sitter, then, was satisfied with a single proof, or he paid extra for further choice, now, he wants them by the half-dozen with retakes gratis, even for the comparatively limited number which we are told are usually printed for a single order. Hence, the negative is cheapened, in a sense, and its storage more costly, and the accommodation required more ample. Granting, however, for the nonce the need—or shall we say the desire?—to save negatives from which prints have been issued, it becomes a matter of some moment to decide how the storage can be best and most economically carried out. For this to be efficiently done it will be necessary that any particular plate required can be most readily found and handled with the least expenditure of time and labour before putting in the printing frame. It would not be possible to describe every method we have seen in use, but a brief reference to what have appeared to us most popular and desirable may be useful.

At the outset a word of warning must be given, as a case which occurred in the provinces some time ago showed

desirable. New up-to-date premises were being erected, including an upper storey for an accumulation of negatives. The building was not constructed satisfactorily, the walls were new, the negatives numerous and heavy, the result, collapse of the walls through the weight being concentrated in the most unsuitable spot. For twelve thousand negatives is not a large number for a business worked at "popular prices"; but they would weigh a ton. Fifty thousand would therefore weigh at five tons, and before such a weight was placed upon the floor whatever, an architect should be consulted. It is not a question of what a floor ought to bear so much as what it is likely to be able to bear that has to be considered. We have in our mind an instance that we have come across, where the most had to be made of a small room on the first floor. The negatives are ranged from floor to ceiling, the walls being entirely hidden, door and window being the only uncovered portions. Here a set of three-inch planks was placed on the floor all round against the wall, and the racks for the negatives were erected upon them, first, with the object of distributing the weight, and, next, to prevent the racks becoming legal fixtures, to effect which they were simply kept in place by being wedged against the ceiling rafters. Then, in the room below his negative room, and without cellarage, a similar line of planks was placed, and on them were erected other planks, as pillars supporting still others pressed against the ceiling rafters. Thus the whole weight of the negatives rested upon the solid earth, and, being put in a perfectly perpendicular arrangement of weight, there was virtually no tendency to side-thrust to endanger the walls. All these precautions were considered on account of the studio proper being, as often happens, an added storey to what, at the outset, was a two-storey building.

To complete our description we should add that there is a similarly supported beam placed under the middle of the room and reaching from side to side to receive the weight of a central erection in the negative room, and which contained a large number of plates.

We have felt justified in describing this particular sample at length, and in laying stress upon the necessity of precautions being taken to ensure the stability of premises where a large number of plates may probably accumulate, from a feeling that the matter is one that may readily lose sight of in the growth of a business, and, further, that the result of want of foresight might bring about pecuniary disaster, or, what would be infinitely worse, danger to human life in the case of a collapse similar to the one we referred to. We will complete our survey of the subject in a future number.

There died last week at Northampton Workhouse, Mr. Charles Monson, a former prominent tradesman of the town. In the fifties of the last century he was a drawing-master and photographer on Leicester Road. In 1858 he removed to No. 40, Newland. His advertisement of that period, in the quaint type of the time, calls him "Professor of Writing, Artist, Photographer, Drawing Master, &c.," and states, "Pupils systematically instructed in different styles of Writing, Book-keeping, Oil Painting, Free Sketching, Perspective Drawing, and Photography." In 1865 he was summoned to Althorp to photograph the present King who, then Prince of Wales, was visiting Earl Spencer. In the sixties he removed to 12, Bridge Street, and was for a long time established as one of the leading photographers of the town at the studio now Mr. C. Law's. Mrs. Monson died, and with her Mr. Monson lost his business hand. In 1873 he sold the business to Mr. Law, who has been there now over thirty years, and removed to Leicester. He returned, poor and old, a year or so, and went into the workhouse to end his days.

WANTED—A BENEVOLENT FUND FOR PHOTOGRAPHERS.

Our confrère Mr. H. Snowden Ward, F.R.P.S., in the September number of "The Photogram," devotes an article to a plea for the establishment of some kind of agency for the pecuniary relief of distressed professional photographers, and thus succinctly tells the story of defunct institutions which have already been formed for that purpose, and have unfortunately "died the death."

"The attitude of photographers to their benevolent associations has been very curious. The earliest charitable fund which was started by the craft was on the lines of a benefit society by which regular and relatively large subscriptions were demanded, and to which members only might apply for relief in time of sickness or distress. It gradually dawned upon those most interested that the photographers willing to subscribe to such a fund were very few in number; and, further, that those who did so subscribe were exactly the kind of photographers least likely to ever make claim upon the funds. (In after years, however, more than one of these original thrifty members came down in the world, received help which he greatly valued from the 'Benevolent,' and fully reinstated himself in a successful position.) After some years the attempt to run a benefit society was felt to be hopeless, and, after various schemes had been considered, it was decided to convert the concern into a benevolent fund, which all photographers were asked to support, and on which all photographers, their wives, and children, should have a general claim if they fell into poverty. At the time of the conversion the accumulated funds, which eventually amounted to some £300, were set aside as a nucleus for a pension fund, and this proved a most disastrous decision, for the accumulated fund, always standing in the books, too small to be used for pension purposes, yet very large in comparison with the funds actually received and distributed for the general purposes of the 'Benevolent,' proved a difficulty in the way of people asked to subscribe. For years the 'Benevolent' was carried on by a very small but very hard-working committee. Eventually the objection to subscribing further funds became so great that it was resolved to take all possible steps to secure the conversion of the pension fund to the general purposes of the association. So intricate were the difficulties under the Friendly Societies Act that in spite of having hard-working and self-denying honorary solicitors, quite two years were consumed in the freeing of this fund; but not a great while elapsed before the whole of it had been spent, and spent very judiciously according to the best belief of the committee, when once the money was released. Eventually the whole funds were exhausted. May I suggest," concludes Mr. Ward, "that the Royal Photographic Society or the Professional Photographers' Association, or, still better, both, might move in this matter? I am well aware of the legal difficulties in the way of the R.P.S. undertaking benevolent work, but I think there is nothing to prevent that society joining with another or with others in calling a meeting to consider the question, or in establishing a joint committee for the administration of a fund."

We have much pleasure in giving publicity to Mr. Ward's suggestion and according it our acquiescence and support. Several prominent members of the Professional Photographers' Association have, we know, had the matter under consideration for some years past, and now that summer is drawing to a close, and the time for the resumption of the autumn meetings approaches, we shall look to some active steps being taken to give effect to Mr. Ward's admirable idea. But the initiative must be taken by professional photographers themselves. For a long series of years we gave the old Benevolent a great deal of personal and journalistic support only to receive in return the studied neglect of those in whose interests we were working. This state of things must not recur. Found your

Benevolent Fund by all means—alas! we know with Mr. Snowden Ward that it is only too urgently needed in many quarters!—yet, *let it be first of all stipulated that the idea secures the immediate practical support of those on whose behalf it is to be exploited*, professional photographers and their assistants, and we shall be only too pleased, as hitherto, to form one of a band of willing workers pledged to carry on the administration of the Fund. But we wish it clearly understood that in the absence of strong and influential professional support we shall not feel justified in devoting either time or space to the matter. Who will come forward to help?

THE REVERSAL OF THE WET-PLATE IMAGE.

Most photographers have had some experience of the results obtained on the gelatino-bromide film when the plate has been unreasonably over-exposed, and in consequence the image develops as a more or less foggy positive. The exposure required to reverse the image is, of course, so prolonged that this result can be obtained unintentionally only by the merest tyro.

Fig. 1.—Print from Normally Exposed Negative. Dry Plate, $\frac{1}{2}$ sec., f. 22. Wet Plate, 1 sec., f. 8. June Midday, Sunshine.

While making experiments in reversal some time ago with dry plates it occurred to the writer that an interesting comparison might be made of the behaviour of the wet collodion with the gelatino-bromide films. The prolonged exposure required for wet plates obviates any chance of obtaining a reversed image by accident, and, as events proved, it is by no means an easy matter to solarise the wet collodion image even under the most favourable conditions. The difference in speed between a gelatino-bromide plate of medium rapidity and the wet collodion film varies from ten to forty times in favour of the former; it is impossible, however, to give any exact figures, as the rapidity of the wet collodion film is affected by stale iodised collodion, cold weather, etc., etc.

The exposures were made in June in full mid-day sunshine. A dry plate of medium rapidity was first exposed for half a second, with the lens stopped down to F. 22. Development showed this exposure to be correct for the subject in hand. Three exposures of five, ten, and twenty minutes respectively were then made for the purpose of obtaining a solarised image.

The plate exposed for ten minutes developed into a very positive (a print from this is shown in Fig. 2). The exposure given for the dry plate in order to obtain a positive in

Fig. 2.—Print from Dry Plate, Showing Total Reversal of Image. Exposure, 10 min. Stop, f. 22.

was consequently about a thousand times that required for correctly-exposed negative.

The wet collodion negative was then taken, and an exposure

Fig. 3.—Print from Wet Plate, Showing Partial Reversal of Image. Exposure, 20 min. Stop, f. 8.

of one second, with the lens working at F. 8, produced a good negative. This was about fifteen times the exposure given

the dry-plate negative; there was little to choose between the two plates, as the greater brilliancy of wet collodion compensated for the use of a large stop. As the two correctly-exposed wet and dry negatives gave practically the same results, only one reproduction (Fig. 1) of correct exposure is given here. The wet collodion plate was exposed for ten minutes, but on development the image showed practically no signs of reversal, and the film was covered with a dense deposit. Another plate was exposed for twenty minutes, of course with the stop at F.8. At this time the result was a partial success, and the image developed as a very feeble, or rather, very foggy positive. As will be seen from the reproduction of a print from this positive, the reversal was anything but complete, and probably the exposure would have to be trebled to obtain a positive equal to that produced from the dry plate. Exposures, however, beyond twenty minutes are practically useless with wet plates, as, after that period the sensitiveness of the film is greatly diminished, and there is also the difficulty of keeping the plates from drying, especially in hot weather. The foregoing experiments prove that though the wet collodion image is subject to reversal in the same manner as a gelatino-bromide plate, an exposure of over a thousand times longer than would be required for a correctly-exposed negative is quite insufficient to produce complete reversal. Several experiments were subsequently made to produce a genuine positive with a wet plate, but none of them were successful, although the conditions of sunshine, subject, time of day, and fresh collodion were all in favour of the attempt.

Prints from a correctly-exposed negative, and from the solarised dry and wet plates, are given here. The extent of reversal in the wet plate can be seen in Fig. 3. J. I. Pigg, F.R.P.S.

A METHOD OF DETERMINING THE FOCAL LENGTH AND THE ABERRATIONS OF A PHOTOGRAPHIC OBJECTIVE.

II.

The accuracy with which the adjustment can be made when ascertaining the focal point (dealt with last week) is at least twice as great as it will be when a distant object is used. For, supposing the screen be moved to S_1 (Fig. 5), a short distance in front of F_2 , then the emergent rays will be slightly diverging, and after reflection at M will fall upon the lens as a diverging beam (Fig. 6), and will be focussed by the lens at a point S_2 behind F_2 . It can easily be shown that if the displacement be small, S_2 is about the same distance behind F_2 , that S_1 is in front of F_2 . Thus the image will be out of focus on the screen (which is now at S_1) by the distance from S_1 to S_2 , that is, by twice the amount the screen has been displaced.

Fig. 5.—Course of Rays incident upon the Mirror M when the Aperture S is nearer the Lens than its principal focus F_2 . The emergent rays are divergent.

Returning to the cardboard model, it will be seen that, with the mirror in position, a rotation of the lens about any other point than n_2 will displace the image: and that in this

case, also, the displacement will be twice as great as when using a distant object, and therefore the position of n_2 can be found with twice the accuracy.

For when the lens is rotated about a point other than n_2 , such as C (Figs. 7 and 8) the ray F_2n_2 is altered in direction by

Fig. 6.—Course of Rays after Reflection in the Mirror M . The divergent bundle has been reflected as a divergent one, and this focusses at S_2 behind the principal focus F_2 .

the motion of n_2 , and therefore the emergent parallel bundle is altered in direction. This bundle, after reflection, will again enter the lens, inclined at the same angle to the normal, and

Fig. 7.—Course of Rays from F_2 to the Mirror M , when the Lens has been rotated about C .

will emerge from n_2 along a parallel line n_2P . Thus, F_2n_2P is practically an isosceles triangle, and F_2P is double the distance which n_2 has been displaced.

Fig. 8.—Direction of Rays after Reflection in the Mirror M . The image of F_2 is at P . The displacement, F_2P , is twice the displacement of n_2 .

But when the rotation takes place about n_2 , as the direction of the ray F_2n_2 is unchanged, the parallel bundle strikes M normally, for all positions of the lens, and returns without deviation, so that the image is fixed.

By measuring the distance from n_2 (the pivot) to F_2 (the screen), the focal length is at once found.

This can be demonstrated by means of the large lens, which

having adjusted the distances to obtain a distinct and stationary image, shows a focal length of 31.15-16 inches.

THE ABERRATIONS OF LENSES.

Spherical Aberration.—I will now show how the apparatus may be used, in a very simple manner, to measure the spherical aberration of a lens. When a beam of parallel light passes through a lens, the tendency of the lens is to focus those rays which enter the lens near its periphery, at a shorter distance than it focusses the axial rays. This defect is termed "spherical aberration."

I insert a small stop and focus the crosswires. The stop is then removed, a circular black card, of which the diameter is a little less than that of the emergent beam, is placed over the mirror and the screen is again focussed. The difference in focal length (i.e., the distance between the two positions of the screen), in the case of the lens before us is $\frac{1}{4}$ in. That is the measure of the aberration of this particular lens at this particular aperture (F.4).

Turntable to take any lens. The lens rests on two V's, adjusted horizontally and vertically respectively. The V's are attached to a carriage, which slides on two steel bars of a cradle; the latter rotates about a vertical axis.

Petzval showed that the aberration varies with the square of the aperture, and with the focal length. Thus the aplanatic coefficient can be defined by $A = \frac{s n^2}{f}$; where s is the above difference between the focal lengths of axial and marginal rays, and n is the "f number." As this lens is of nearly 32 inches focus and is working at $f/4$,

$$A = \frac{\frac{1}{4} 4^2}{32} = \frac{1}{8} = .125$$

The coefficient, as defined above, will be the same for lenses with varying focal length, and working at any intensity, if they are equally well corrected.

Astigmatism.—When light passes very obliquely through a lens, radial and transverse lines are focussed at different distances. This effect is called "astigmatism." Having explained the error by means of a diagram, I will show that it can easily be measured with this apparatus. A piece of thin zinc, in which

horizontal and vertical slits have been cut, is substituted for the slanting crosswires. The lens is turned through a large angle so that its axis produced would meet the screen at the point distant r from the slits. The screen is adjusted until the image of the vertical slit is sharply focussed and its position noted. It is then adjusted until the horizontal slit is sharp. The distance t , between the two positions of the screen, measures the astigmatism of the lens, at that particular obliquity. The astigmatism varies as the square of the obliquity, and directly as the focal length. Thus, to define the coefficient put

$$\text{Astigmatic coefficient} = T = \frac{t}{r^2}$$

In this case t is $\frac{1}{4}$ inch, and r is 10 inches. Thus T is

$$\frac{32 \times \frac{1}{4}}{10^2} = \frac{8}{100} = .08.$$

T , thus defined, is a true coefficient, for it has no "dimensions" and will, for instance, be the same for a series of lenses accurately constructed to the same formula, but of different focal lengths. It will be the same if the measurements are in inches or in centimetres (they must all be in inches, or all in centimetres, of course).

Curvature of Field.—Placing the lens once more with its axis normal to the screen and focussing the crosswires, a rotation of the mirror causes the image to travel across the screen. As the light falling on the mirror, and, therefore, also the light returned by it, is parallel, the image is always that of an infinitely distant object. Thus, if the lens have a flat field, the image should remain sharply in focus right across the field. It does not remain, however, sharply in focus, and at a certain distance r from the centre, the screen has to be moved $\frac{3}{8}$ in. before it comes into focus (the crosswires being at 45 deg. with the horizon, not horizontal and vertical, to avoid difficulties due to astigmatism). Let the distance the screen is moved be k , was measured and found to be 8 in. Then the curvature coefficient can be defined thus—

$$\text{Curvature coefficient} = K = \frac{f k}{r^2}$$

$$\text{In this case } K \text{ is } \frac{32 \times \frac{3}{8}}{8^2} = \frac{3}{16} = .18.$$

I would point out, however, that as flatness of field is only of importance in copying, it will be fairer to the lens to measure the coefficient for "copying the same size" than for parallel light.

Chromatic Coefficient.—By inserting behind the aperture in the screen coloured solutions (iron sulpho-cyanide and ammoniacal copper sulphate, for red and blue respectively) the chromatic aberration can be measured. The coefficient is $C = \frac{\Delta}{f}$ where Δ is the difference in focal length for the two colours.

REG. S. CLAY, D.Sc.

A VIKING Magnifying Glass.—At the recent visit of the German Society of Anthropologists to Stockholm (according to the "Standard's" Berlin correspondent), the theory was put forward, for whatever it may be worth, that an object in the Historical Museum may have been used by the ancient Vikings as a magnifying glass. On the German men of science being shown some beautiful gold and silver filigree work, Professor von Förster, an oculist, expressed the opinion that the fixing of the little grains could not have been performed with the naked eye. This led to the Museum authorities producing an exhibit belonging to a Gothic discovery at Wisby in 1877. On close examination this proved to be a piece of rock crystal about two inches in diameter, half-spherical in shape, the side underneath being slightly convex, which was capable of magnifying objects to twice their size. The glass was found with two small folding scales and a set of weights, such as were used in the time of the Vikings for weighing gold and silver.

NEW ORDNANCE SURVEY MAPS.

REPORT of the Ordnance Survey to March 31 last was issued the day last week as a Blue-book. From it we see that a great advance in small-scale work of the department has been made, and several small-scale maps have been completed; also that good progress has been made in the revision and re-survey of the 25 in. and 6 in. scale maps. The last of the 1 in. outline maps of Ireland has been published, thus completing the revision of the United Kingdom and making available for the public a 1 in. map of the United Kingdom on one uniform system. What will probably more interest tourists, photographers, and cyclists is the issue of small-scale maps folded in covers, and printed either on thin, tough paper, or on thin paper mounted on linen, has been considerably extended. We are pleased to learn that a new method of folding in covers has been introduced which enables the map to be referred to without the trouble of opening it fully. This is a great convenience when on tour.

It may not be known to many of our readers that the maps issued by the Ordnance Survey Office are produced by photography, which, as the work shows, has been brought to a very high state of perfection at Southampton. The maps are first drawn on a large scale—towns, we think, on the scale of something like ten feet to the mile, small towns and villages on a smaller scale. These large maps are then reduced by photography to the smaller scales. But a little consideration will show that when the large maps are much reduced, the roads, lanes, footpaths, and the like, together with the names, will become so small as to be almost indistinguishable. Therefore in the smaller maps these have to be emphasised, the roads, lanes, paths, etc., made wider, while their relative widths must be preserved, and the names made larger. For example, a lane or path and its name which, if it remained as the reduction would make it, would be too small to be of much real value. This is remedied in a very ingenious manner at Southampton by what is there known as the "blue process." This process, it may be mentioned, is in no way related to the blue (ferrocyanide) process so generally employed by engineers and the like.

The Southampton blue method is this:—An impression from the zincographic map plate to be reduced is printed in a pale blue (actinic) ink which shows all the detail. Then the lines are traced over with a strong black ink, keeping outside them to the necessary extent; the same with lanes, paths, etc. In doing this the relative widths of them are carefully preserved, and instead of forests and woods, which, in the large-scale maps are represented by a large number of trees, only a few are put in according to the acreage. The lettering is also done on a larger scale so as to be readable, which would not be possible in the reduction. This work has been reduced to such a system in the Ordnance Survey Office that it is almost mechanical. When all this work is completed, the blue print with its black lines is photographed to the scale desired. In the copying, photography ignores completely—by reason of the actinic quality to the pale blue ink—the original blue print, and only reproduces the black lines in the negative. This process, if more generally known, might sometimes commend itself in other directions where reductions are necessary from large originals of line subjects—say, plans, and the like.

ISLE OF WIGHT Photographic Society.—The second photographic exhibition of this society will be held in the Medina Hall, Newport, I.W., on October 19 and 20. There will be six open classes, in which silver and bronze medals will be placed at the disposal of the judges, who are Messrs. F. C. Lambert, T. Perkins, and Colonel R. V. Malden. A gold medal will be awarded to the best picture in the open classes. Entry forms, etc., can now be obtained from the hon. secretary, J. Howard Burgess, 55, Pyle Street, Newport, I.W.

AMERICAN NEWS AND NOTES.

A DEMONSTRATION OF PHOTOGRAPHY IN COLOURS.—What is said to have been the finest demonstration of photographs in natural colours ever given in St. Louis took place recently in the German Pavilion at the World's Fair, when a representative of the Royal Polytechnical School of Charlottenburg gave an exhibition in the organ gallery. The demonstration was the same as that given before Emperor William of Germany.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The usual quarterly dividends of $1\frac{1}{2}$ per cent. (being at the rate of 6 per cent. per annum (upon the outstanding Preferred stock, and of $2\frac{1}{2}$ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common stock, have been declared by the Eastman Kodak Company of New Jersey, payable on October 1, 1904, to stockholders of record at the close of business on August 31, 1904.

MILTON WAIDE, the well-known "One Man Method" photographer of 164, Fifth Avenue, New York City, is about to launch a perfected system of teaching by use of mail and express companies. His method is intended both for professional and home window portraiture for amateurs. He believes his system of teaching will be practicable and thorough, and price of tuition will be within the reach of every one. The prospectus is now ready, and will be sent to any one on application. It contains valuable suggestions and half-tone illustrations of his novel print and mount effects. Mr. Waide uses exclusively artificial light developing papers.

PHOTOGRAPHY IN THE U.S. ARMY.—One of the recent developments that marks the growing importance of photography is its recognition by the U.S. Army, in which a corps of photographers has been established. "Wilson's Magazine" for August says: "Photography has for a number of years played an important part in connection with the movements of the army, but has only lately been officially recognised. Its importance in providing data for the engineers in mapping out a plan of campaign, or in laying out a line of march through hostile countries, can hardly be over-estimated. It is more than probable that one of the early developments in this kind of photography will be the introduction of the kite or balloon in conjunction with the camera. The field presented in the army manoeuvres for the practical use of the camera is boundless, and it is only a matter of surprise that it has not long ago been recognised as one of the necessary adjuncts to a campaigning army."

PHOTOGRAPHING A SHOP WINDOW.—I watched a man photograph a shop window the other evening, and his method interested me greatly (observes a writer in the "St. Louis and Canadian Photographer"). He first went inside, and with some tissue paper and a few rubber bands, gave each of the incandescent lights a jacket that reduced their intensity greatly, while cutting off but little of the light. An exposure was then made of several minutes' duration. The lens was capped, an assistant left to guard the camera while the tissue paper covers were removed, and then a second but much shorter exposure given. I went around and asked the proprietor to let me see one of the pictures, and they were simply fine. The method certainly looks very practical, and a few experiments should enable one to secure most pleasing results. A still better plan would be to secure the required number of ground glass lamps, but this would mean quite an outlay on account of the varying form of sockets and voltage of the currents.

A SIMPLE EXPERIMENT.—An amateur came to me recently with a negative he had been spotting, and on which he had

made a rather mussy job, writes Fayette J. Clute in "Camera Craft." He had been using his colour in too liquid a form. The first thing to do was to remove his work, which was done by soaking the negative in a tray of clear water, and occasionally passing a tuft of cotton over the surface. By the time his spotting was all removed the film was thoroughly softened. Noticing that the negative was on the weak side, and also wishing to save time, I blotted off all surface water by placing it between the folds of a towel, and then held it pretty close to the gas-jet to dry—in fact, so close that it became pretty warm. My friends protested that I would melt the film—he had tried the same thing with disastrous results. The film did not melt. The truth of the matter is, that a negative once dried and again softened in water will stand during the second drying an enormous amount of heat. What is also interesting is the fact that a negative so treated improves in contrast much as does one subjected to the regular methods of intensification. This is not so much due to the second wetting as to the drying of the negative so rapidly. Try the experiment with a waster by thoroughly wetting one end only, and then drying it rapidly. A print from the entire negative will tell the story. I believe a repetition of the treatment will still further improve a flat negative. The same rule holds good with the original drying of our negatives.

THE CAMERA AS AN AID TO WRITERS.—In these days of the illustrated magazine, a camera is almost invaluable to the writer, remarks Campbell B. Caesar in "The Photographer." The illustrations will oft-times sell an article, even when the text is not up to the mark. Good photographs always hold the editor's attention. This statement holds good not only with illustrated articles, but in fiction as well. In what way can a story be more realistically illustrated than with photographs? Another market for the amateur photographer may be found in the many photographic contests which are frequently announced in the principal pictorial magazines and newspapers. The prizes, in some instances, run as high as one hundred dollars or more; and even if your contribution fails of winning the offered premiums, if it is good it will probably be purchased at a fair price. Again, an editor often accepts a manuscript on condition that the author secure illustrations. The result is that, lacking a camera, he must spend half a day seeking a competent newspaper photographer, and must pay him a considerable part of his profits on the story for taking the photographs. The cost of illustrating a single article in this manner is sometimes more than large enough to cover the cost of a good camera. The size of camera most useful for practical work in this line is the 4 by 5 or 5 by 7, preferably the latter. The cost, anywhere from a few dollars to two or three hundred. Two weeks' time, together with a fair amount of intelligence, will give one the necessary skill in using the instrument. Until all the minor details of photography, such as developing, printing, and so on are mastered, the local photographer will develop and print the work for the modest sum of from six to ten cents each. Excepting the typewriter, surely the camera is the most useful mechanical appliance the writer can have.

HOW AFRICAN ABORIGINES AT THE ST. LOUIS FAIR TREAT PHOTOGRAPHERS.—There was uprising of the African pigmies at the Fair last week, and bloodshed was narrowly averted, says the "Photographer" (New York). They attacked a photographer who had taken a picture of them. One of them drew a knife, and several picked up rocks. They were driven back into their kraal by the Rev. S. P. Verner, who brought them to the Fair. Bert Underwood, president of a stereoscopic view company in New York, negotiated with the pigmies for a photograph, through Bogobo, their interpreter, and they agreed to pose for

a nickel apiece. As there were seven, that meant thirty cents. Mr. Underwood paid the price, and got ready to take the picture, but they balked, and made him pay them another thirty-five cents. Mr. Underwood then took the picture, and his assistant picked up the camera and a short ladder which he had used, and started away. Before they had gone twenty feet the pigmies decided that they had been too easily headed by Bogobo, they went, yelling, after the photographer. Overtaking him east of the Trading Post, they seized the camera and ladder and tried to tear off his coat and take everything they could lay their hands on, all the while clamouring for more money. When the money was not forthcoming Archibald, the little cannibal, drew a dangerous-looking knife and some of the others picked up stones. Mr. Underwood broke away from the band of howling Africans, and turned back toward the kraal, looking for somebody who had control of them, and could protect him from them. He found Mr. Verner who had been a witness to the compact, and appealed to him. Mr. Verner said the agreement had been that they would be photographed for five cents apiece, and he compelled the pigmies to go back to their enclosure. Mr. Underwood says the savages were instigated and led by Bogobo, the educated African, who acts as their interpreter. There have been several similar outbreaks, in which the Africans have used knives and stones to intimidate photographers into giving them money. Complaints have been made against their conduct, and promises have been made that a guard would be stationed at their kraal to protect visitors from them. It is feared that unless they are restrained they will sooner or later attack a white man who will fight, and blood will be shed.

TREATMENT OF THE NEGATIVE BEFORE PRINTING.—A great deal may be accomplished by working on the back of the negative, and there are several ways of doing this. In "The Camera" for August various methods are suggested. A varnish or collodion containing a very little yellow colouring matter (for instance, alcoholic tincture of turmeric) may be poured over the back of the plate if there are large portions of the image too weak to print well, while those corresponding to the denser parts of the plate are scraped away so that they may not print chalky white. Another method, and perhaps a preferable one, is to cover the back of the negative with tracing paper—"papier minéral,"—or onion skin. This paper has a non-uniform structure, different from the ordinary tissue paper. It is cut into pieces the size of the negative, and slightly dampened on both sides with a clean sponge. A narrow edge of paste, say $\frac{1}{4}$ in. wide, is to be applied to the borders of the glass side of the negative, and the wet tracing paper brought down so that it will adhere by its edges only. Care must be taken not to smear the paste either on the negative or on the paper, as it would render the parts touched unequally transparent. The paper, too, must be laid down evenly, and not drawn too tight, otherwise when dry it will be puckered. If well done the paper, when dry, will be perfectly smooth and tight, and will be in just the right condition to be worked upon with an artist's stump. Let us suppose that we have a landscape negative to deal with, which presented a foreground with good though weak, detail, distance perfect, and sky entirely too dense to give effect of atmosphere. After getting the paper on we would fill the small end of the stump by rolling it in the powdered crayon, obtained by scratching down a soft black crayon with a knife. We should now apply the stump with its heavy charge of black dust first to the sky, so as to make it entirely non-actinic, and to prepare it for subsequent introduction of printed-in clouds. As the tracing paper receives the lead best at the first touch, we should follow the distance with great care, and renew the crayon powder whenever the stump refuses to give a good black mark. The rest of the sky should be filled in without any great caution, save that

making it perfectly dense. The stump, which we will suppose exhausted, or very nearly so, might now be very slightly tied to the paper over the weak, thin parts of the foreground, and the work equalised either with a ball of cotton on the tips of the fingers. It must be remembered that, over the parts of the negative, such as the half-tones, and the transparent parts in general, the stump-work has great draining power, and will appear prominently in the print unless properly managed. Beginners would do well to have a piece of sensitised paper ready to try the effect before setting the negative aside as finished.

NOTES ON RADIO-ACTIVITY.

II.

ESTIMATION OF ACTIVITY.

The time occupied by uranium to discharge an electro-negatively charged electroscope is noted by a watch and is designated "unity," a telescope and micrometer scale are necessary for the purpose. The instrument is simple and reliable, avoiding an elaborate and costly mechanism. It consists, as you observe, of a wooden framework, with glass back and front, one side being ground glass. In the centre is a simple, improvised electroscope. A positive charge is recorded the leaf by the aid of a camel's-hair brush. We now note how long this charge will remain; usually it will do so for a day or more. Markings are made on the ground glass at certain intervals, on bringing a known weight of pure radium bromide, preferably in a metal box, to within a distance of a yard, we note the time taken for the leaves to fall. Then if a pure sample causes the drop in sixty seconds it follows that the same weight of another specimen doing the same work in 120 seconds is only 50 per cent. pure, and so on. By this method the β and γ -rays are not measured directly (the γ -rays do not come in at all, as they do not penetrate the metal box). What is measured is the ionisation of the air produced by this 1 per cent. of the total radiation.

Either the impact of the negatively charged corpuscles or β rays (electrons) or the sustained agitation resulting from the γ -rays (ether vibrations) render the air electrically conducting, and thus the charge leaks away in proportion to the rays producing the ionisation.

POLONIUM.

Soddy claims that Markwald's radio-tellurium is identical with polonium. Markwald obtained, he says, only 4 Mgm. of his radio-tellurium from eight tons of pitchblende, and he says this body does not decay. I think Soddy has vindicated his position; Markwald should have done better not to rename Madame Curie's polonium. Madame Curie states in her thesis that a specimen of bismuth-nitrate containing polonium lost half its activity in eleven months. Its radiation is propagated only 4 to 6 Cm. in air.

SCINTILLOSCOPE.

By employing a glass screen of zinc sulphide, as suggested by Rutherford, the scintillations from this α -radiation produce a good effect on a black ground. There is no diffuse lighting, as in the case of a spintharoscope. It is possible to view the actual bombardment on pitchblende itself. Very thin films of gold, silver, of mica and celluloid allow these rays to pass. By using this screen and a revolving wheel, Glew found the duration of a scintillation to be less than 1/50,000th of a second. These polonium discs may be coated with a celluloid film to protect them, which is washable and sterile, e.g., in therapeutic use.

¹⁸ Gw., P.J., 1/1904, p. 440.

¹⁹ Archives Roentgen Soc. ety., June, 1904.

BLONDIOT'S RATS.

In abstracting all the recent work on this subject I have come to the conclusion that the effects described are in all probability subjective or due to warmth, or to the changing activity of the eye in the dark, or to the natural decay of the sensitive calcium sulphide.

RADIO-ACTIVITY OF THE AIR.

It has been demonstrated that the ground air is often radio-active, the supposition is that substances producing a radio-active emanation similar to that of radium are distributed among the constituents of the soil in question. It may be mentioned that a large boiler full of ordinary atmospheric air was kept closed for six weeks; the air was then examined without any activity being found to have developed, confirming the view that it probably comes from the soil in all cases.

RADIO-ACTIVITY OF MINERAL WATERS AND MINERALS

The activity of the gas collected from the source of Buxton water was found to fall to half value in about three and a half days (the corresponding time for the radium emanation being 3.7 days, Rutherford). It has been suggested that the gas thus collected might be employed therapeutically.

Strutt¹⁸ read a paper before the Royal Society dealing with this matter, and the examination of minerals for radio-activity. His method for the latter is simply to heat the mineral in a crucible and to examine the rate of decay of the emanation evolved. The results he claims are definite, and can be obtained by working on small quantities. A mineral called monazite, from Norway, though containing no radium, yielded helium in fair quantity.

Bath water contains a large proportion of sulphates; radium sulphate is probably soluble only to the extent of about 1 in several hundred thousand parts of water. It follows, therefore, that the radium is found here chiefly in the deposit and not in the water. It was calculated roughly that 0.5 Gm. of radium is deposited per annum, the total deposit of mud, etc., being about 500 (500) kilos. per annum. The volume of gas yielded is about 100 cubic feet per diem. This had been previously found to contain helium to the extent of 1/1,000th of its volume, i.e., 3 litres per diem or 1,000 litres per annum. It is concluded that the proportion of this "end product" to radium is about of the same magnitude as in the radio-active minerals. The spring probably draws its supply from minerals of this nature. Droitwich brine¹⁹ on boiling yielded a radio-active gas, and Russian mud baths possess²⁰ radio-activity, and have an inhibitory action on bacterial growth.

A new radio-active mineral from Ceylon was examined by Dunstan, and independently by Ramsay, and the latter found it very rich in helium.

THERAPEUTIC USE.

The fact that radium rays penetrate both bone and flesh to an equal extent has up to the present prevented its use for skiagraphic purposes, and there is, in addition, the difficulty of the irritation which may be produced on the part or the body during such process.

The β -radiation has an inhibitory action on many organisms, e.g., that of typhoid, anthrax, diphtheria, *B. coli*, and many others. Bacterial colonies exposed three days to the β - and γ -rays emitted by 10 Mgm. of radium bromide, and removed to a photographic plate, affected the plate even through a double layer of lead foil.²¹ The extraneous micro-organisms in vaccine lymph may be killed off by the aid of the radiation.

Sir Oliver Lodge inclines to the opinion that radium for medical purposes will replace almost every other source of radiation. He believes the beneficial action on rodent ulcer is due to the oxidising power of air ionised or ozonised by the rays; this, he concludes, is the reason why deep-seated cancer has not as yet been benefited. What is necessary is potent oxygen, produced, for example, by injecting hydrogen peroxide and rendering the latter active by penetrating rays. The oxygen must be in an unstable form such as

RADIUM APPLICATORS (McLEOD)

exists in arterialised blood. If this is not the healing factor it remains to be found out what is the actual cause, and to introduce this factor as near as possible to the diseased part.

You will be aware that the thorium emanation²² has been tried in phthisis, and it appears that this has bactericidal properties, and some satisfactory results are recorded.

McLeod²³ has tried radium in lupus vulgaris, both the nodular and verrucose varieties, rodent ulcer, epithelioma, and in two cases of cancer of the cervix uteri. Reports of these last two important cases are still pending. He is convinced the β -rays have the inhibitory effect on bacteria, and, readily passing through glass, have the chief therapeutic value in addition.

It would appear that the rays, like the X-rays, are cumulative in effect, causing a cellular degeneration of weakly resistant diseased cells, and this, having reached a certain degree, an inflammatory reaction is secondarily produced, and as this occurs in impaired tissue an indolent ulcer is the result.

In rodent ulcers radium acts like a charm—it has been found a valuable adjuvant to the Finsen light and X-rays, and on account of its small bulk it is useful in positions difficult to get at, such as the eyelids and the mucous membrane of the nose. Other workers have used radium in psoriasis, epithelioma of the orbit, orbital neuritis, acute iritis (relieving pain), and in superficial malignant diseases, disappearance of growth, and in cancer of the breast with relief of pain.

MacIntyre²⁴ has reviewed the recent work on X-rays and radium and is of opinion that polonium may have importance therapeutically. He tried radium in a sarcoma of the neck by introducing it in quantities to the interior of the deeply-seated diseased tissue.

Reginald Morton²⁵ confirms the therapeutic utility of radium. Two cases of cancerous throat are stated by Walsh and Morton to have greatly improved under the rays. The glass tubes, as suggested by Mackenzie Davidson, are undoubtedly the most satisfactory, as they obviate the moistening resulting with mica screens; applications are made for half an hour every second or third day according to the activity of the radium.

THE RADIUM ELECTROSCOPE.

I have here an ingenious little mechanism showing radium work. This instrument, a modified form of that devised by Stieglitz, has a tube of radium supported *in vacuo*. The electro-negative rays penetrate the glass, thus leaving a plus charge behind which causes the attached aluminium leaves to diverge. When the leaf touches the side of the vessel which is connected to earth it lapses and commences to charge up again.

It has been arranged by Glew²⁶ to ring an electric bell at contact—a coherer, as used in wireless telegraphy, is actuated each discharge as you have heard. A description of the coherer and other parts of the instrument may be found in the "Photographer's Journal" and in "Nature" for July 14 last.

W. HARRISON MARTINDALE

THE FAILURE OF AMERICAN PHOTOGRAPHY AT THE ST. LOUIS EXPOSITION.

[On August 19th we promised Mr. Alfred Stieglitz, who writes on the subject, that we would reprint his projected reply to an article from "The Photographer," of New York, that was reproduced in these pages, dealing with the causes of the American photographic fiasco at St. Louis. We append Mr. Stieglitz's reply to Colonel Ockerson. The matter, however, is not one that can further be pursued in these columns.—Eds. "B.J.P."]

COLONEL OCKERSON'S statement regarding his correspondence with me does not exactly fit my recollection of that correspondence. Were I not 4,000 miles away from home, seeking rest and recuperation, I would gladly send you copies of the entire correspondence in order that your readers and the photographic world at large might have the opportunity to judge for themselves what Alfred Stieglitz, director of the Photo-Secession, actually demanded when approached by the managers of the Liberal Arts Department to lend a helping hand in making the pictorial photographic section at the St. Louis Fair a success. Could not Colonel Ockerson produce this correspondence in view of my absence? I shall give you the substance of the request made by me in reply to letters received asking me to help the photographic section. It must be remembered that before I had been approached directly a year had elapsed, during which the photographic press and various photographic organisations had helped to make a seeming mess of things, that Mr. Caffin had in the "International Studio," a year before, warned the St. Louis authorities that the best American pictorial photographers would not accept the terms as originally proposed by the St. Louis management, and would stand aloof, etc. That all history to those photographers who are really interested in the matter and have followed the course of events. In reply to Colonel Ockerson's letter calling on the Photo-Secession to participate in the Liberal Arts Department exhibition, I wrote fully to him explaining the aims of the Secession and what it had accomplished.

²¹ P.J., 1/1904, 722.²² L., 1/1904, 1121.²³ L., 1/1904, 1336.²⁴ B.M.J., 1/1904, 933.²⁵ B.M.J., 1/1904, 941.²⁶ Glew, Nature, July 14, 1904, 246.²⁷ Photo. J., 1899, p. 179.

ad, and that in order to remain true to itself it would have assist that the St. Louis authorities invite it as a body to send collection, such collection to be submitted to the National Jury artists; and that such photographs as might pass that august be hung in the Fine Arts Building and the balance in the al Arts. Further, that some photographer be added to the of artists for the purpose, and, realising as I did that some of painter-jurors might construe this as an insult, and not wishing seem uncompromising or to throw unnecessary obstacles in the of those whose road I knew was obstructed with all sorts of acles, I suggested that either Mr. Steichen or Mr. Eugene, both ters of repute, and both first-class photographers of fame, would satisfactory. At this time I had no idea that Mr. Steichen, a later, would be invited to send two of his paintings for exhibi- at St. Louis in the Fine Art Department *without submission any jury whatever*. Here you have proof positive that not anything had to go before a jury, even if the United States Steel acquiesced—in theory. Naturally, and as I expected, my test was not accepted. The declination was couched in very illiatory terms. I was assured that all that was possible would done for pictorial photography; that for this reason and that, demands could not be acquiesced in; but that I should, never- less, do my utmost to help along. Being more than desirous to American photography well represented at St. Louis if that could accomplished without loss of self-respect and entirely giving the principles for which the Secession stood, I then wrote to nel Ockerson and asked that a written guarantee be given that east one picture be hung in the Fine Arts Building. Being of aspicuous nature—a child, having burnt its finger, is wary of I wanted the assurance in writing. In reply I received a munication assuring that there would be more than one photo- h—many, in fact—in the Fine Arts Building. As this com- ication did not come from Professor Ives, but from Colonel erson, I still was not satisfied. That my attitude was correct roven by what ultimately happened. And please remember I also assured Colonel Ockerson that I was simply talking for Secessionists; that the photographers at large apparently did believe in my principles nor in my methods; and especially in mind the fact that I did not insist that the one picture was e a Secessionist one, but *any* satisfactory to the National Arts y; and that if given proper guarantee I would even at that date assure the Liberal Arts Department of a large Photo- sion collection that could be hung wherever the management of Fair desired! At the same time I positively refused to have thing to do with any secondary jury of photographers, as that too childish and undignified to consider. This is the gist of correspondence, not the exact words, as I have not the letters h me. It must also not be forgotten that I took a similar tion in regard to the World's Fair in Chicago, 1893, and Paris, 0, in connection with which exhibitions I had been approached arrange collections of American pictorial photographs. My fight been for the recognition of pictorial photography, and I have n fighting for twenty-two years and have not swerved an inch. I designated me, in your valuable columns, as "dictatorial." hom have I dictated? To those few who have voluntarily here about me? And have not the photographic organisations, n—the one thousand and one—and the photographers—the 00,000—supported the St. Louis Exhibition? Surely they were subject to my dictation. Why is it, I would like to ask, that just here seems to be a tendency on the part of certain elements in photographic world to lay every failure at my door? I might e add that for the very causes that made St. Louis what it is, Secession will stand aloof from supporting the Salon announced New York this winter. Enthusiasm and ignorance combined dangerous foes to that recognition for which we are battling— friends, unconsciously sham, are its bitterest enemies. And for the English Collection, permit me to call your attention to fact that the *British Government* appointed three "Linked ng" members to arrange it—sent one of these men to hang the ibition; that the British Government has appointed a fourth "Linked Ring" member as International Juror; that the whole ense is borne by the Government. Also remember that Great ain has hundreds of well-organised, active photographic societies amongst these the Royal—yet that it has not demanded that h organisation appoint a judge and that the general body select

the pictures. None of that sort of red tape and playing to the gallery, so as not to tread on any one's toes! And because the British Government handled the question in a dignified manner, the results are dignified and the collection what it is. And how much mud-slinging has there been at the "Linked Ring" for having undertaken the thankless job? Practically none! Imagine the case transplanted to the United States! And also note that in this "Linked Ring," this select body of photographers, some fourteen Secessionists are enrolled.

If it is thought that St. Louis is conclusive proof that the United States plays a secondary role as compared to Great Britain, it might be well to address Messrs. Annan, Evans, Davison, Warburg, Cadby, of England; Demachy, of Paris; Henneberg, Spitzer, and Kuhn, of Austria; Juhl, Matthies-Masuren, of Germany; all authorities upon this question."

SIMPLICITY.

THERE is a peculiarly strong charm attached to the simple. What it is due to it is hard to say. Probably not to one characteristic, but to several. One may lie in the fact that the simple, being the exceptional, acts as a foil and contrast to the major amount of the involved and complicated in life. This appears to be borne out by the simple being more particularly appreciated by those of higher mental powers and social position, who ordinarily have more to do with the intricate, the many-sided and detailed. On the other hand they whose every-day problems are simple, and not complicated by side issues and qualifying considerations, are attracted rather by the involved and complicated. The character of the arrangement of a workman's house, for instance, is very different to that of his master's, if the latter be a man of taste and education. In the former there is an excess of detail. Admiration of the complicated and involved is shown in the pattern of the wallpaper, the abundance of detail and variety of colour in the pictures upon the walls, in the minute elaboration of their moulded or fretwork frames, and in the clustered ornaments upon the chest-of-drawers. It is very conceivable that a man who has spent his day engaged in one monotonous kind of work, watching the uniform travelling of a self-acting planing machine, a drill piercing the same-sized holes in a plate of metal, or turning out by hand the same portion of a boot over and over again, may find pleasure and rest in turning his eyes when the day's work is done upon something involved and intricate. It balances the mind, as it were. For the same reason, he whose day's work has been amidst the involved calculations of the engineer's or stockbroker's office, or who has had to attend to the multiplicity of varied demands in the management of a works or factory, would probably crave for the balancing effects of contrasted simplicity. His front lawn is a restful expanse of plain grass, and not split up into fragmentary flower beds bordered by oyster shells, the walls of his rooms are papered or painted in one plain and subdued colour, and the pictures do not compel immediate attention by vividness of colour, assertion of detail, or elaborateness of frame. In short, a wise simplicity prevails.

Applying these considerations particularly to photographic pictures, those loaded with detail please the one order of liking, pictures with restful lowering of detail and suggestive spacing please the other. One is of the lower, and the other of the higher order of taste and intelligence. A ready and fair test of taste—generally, although not invariably a matter of education, conscious or unconscious—can be gained by noting the amount of accessories, and character of background that the subject elects to have in the picture when being photographed himself. One will have as much, and the other as little as possible. There is no reason why the sitter should not have all he wants. It does not cost a scrap more to anybody. The professional wisely recognising the line of least resistance to the amplest amount of business, gives, as a matter of fact, as much as he reasonably can. He does not keep his studio open to teach high canons of taste, but to increase his banking account. The non-professional worker, however, is not bound down by such considerations, and has the opportunity of following a higher line. In doing so, it will be found that it is in meeting the unconscious craving felt by those of higher mental calibre and taste for certain broad qualities that the success will be gained which stamps a picture with highest merit. This goes far above mere kind of work, and can give character to all kinds. Simplicity is one such quality. It may be expressed in por-

traiture, landscape, seascape, 'architectural' work, animal studies—anything in short. Wherever expressed it elevates result. It requires something beyond a knowledge of photography to do this. Indeed, it is questionable whether over attention to the photographic side does not tend to cripple effort. It is so much easier to take a photographic picture than not to. The charm of the sparkle of the picture upon the screen is oftentimes irresistible. It overcomes thought of deeper purpose, and even of consideration of how much of its glittering quality it is possible to catch. It cannot be caught we find when too late. The river does not flow in the print, nor the wave break. The glowing sand becomes mud, and even the sunshine is only a flare of white. The result is a slight feeling of disgust at the limits of photography. This would be less marked, and give greater stability to effort, if work were less emotional and more marked by purpose and thought.

The inability to express fully also applies to the picture with lowered detail in the effort after simplicity. Photographic limitation has to be accepted, but the less the detail, the less room for technical fettering. If the quality of simplicity be aimed at, there should be careful selection for the special purpose. The charms of the merely pretty that tempt photographic workers so powerfully should be particularly avoided—for this special purpose, that is, for nothing is said against pretty things, but everything for them, in their place. But to appreciate the comparative worth of broad natural simplicity and mere prettiness, let the reader think for a moment which of the two types has made the deeper impressions upon him in life. Is it the pretty fairy glen, containing the crushed up wealth of pebbly brook and overhanging tree, of rock half-concealed by fern, and rustic bridge; or the plain expanse of moor, with the road soon lost in its suggestive breadth, spite of its first bold strike forward in the foreground? When the mind of a man gets into its half-thoughtful, half-dreamy state, does it dwell upon the former or the latter? Upon the pretty rose-covered cottage, or the simple and rugged mountain side? Upon the polish, glitter, and varnish of the assembled yachts on a summer's day in a picturesque home cove, or upon the rough, plain trading brig on a distant and solitary sea? To fill up the measure of the argument, which is the more truly and lastingly attractive, and which wears the better, a pretty wife or one gifted with some of those broad qualities that confer the adornment of true simplicity? It is not contended that many other important factors do not figure in determining liking in such cases as those instanced. But whatever the emotions, if they are strong, they are certain to be characterised by simplicity. Deep emotions respond most readily to simple means. The stately simplicity of biblical language is a ready instance to the point. The same applies to pictures, whether produced by the brush or the camera. One great advantage of the brush over the camera is that it can express less—in other words, be more simple. The contention would thus be that the effort should be to express as little as possible, but of the right kind. The best means is, naturally, by selecting carefully the subject, and, in the case of portraiture, by giving as little accessory, and as plain a background as possible. Material further aid might probably be gained by such manipulation as that referred to in a recent article in the JOURNAL, under the title of "Mental Equipment," in which the possibilities were put forward of blotting out undesired detail in a print by the use of Chinese white, strengthening desired strong features, and then rephotographing the worked-up print—the process of the block-maker, in short, used by him who took the first negative, and who, presumably, had the truest conception of and feeling for the subject.

A CINEMATOGRAPH Mischief.—The second "house" at the Gaiety Palace, Birmingham, ended most unfortunately on Monday night. As a rule the programme concludes with an exhibition of cinematograph pictures, and on Monday night, just at the outset of this exhibition, the apparatus caught fire. There was a sudden flare up and a buzzing sound, and, as may be expected, these unusual occurrences caused much excitement among the members of the audience. The specially erected box which contains the apparatus is situated at the back of the pit beneath the gallery, and the occupants of the pit were the first to realise what had happened. There was a hurried rush to get outside the theatre, and some one foolishly cried "Fire," which spread the excitement to other portions of the house very quickly. Fortunately the result was not so serious as might have been the case. It is a tribute to the excellence of the Gaiety exits that the pit was cleared in about two minutes.

New Book.

"Three Colour Photography." By A. F. Von Hübl. Translated by H. O. Klein. 148 pp., illustrated. Published by A. W. Preece and Co., 109, Farringdon Road, London, E.C. Price 3s.

The introduction to this valuable book takes the form of a review of the principal methods of colour photography that have been introduced since the time of Becquerel, Seebach, and Poitevin. In reference to the trichromatic system of reproducing colour the conclusion is arrived at that "the problem of colour decomposition by photographic means can be considered as solved, as by employing different sensitisers and light filters the conditions of sensitivity can easily be regulated, but the recomposition of the three-colour pictures by means of printing leaves much to be desired. Especially the production of the photo-mechanical printing surfaces is not certain if a very accurate reproduction of all the delicate gradations is wanted, and also the printing process itself lacks that uniformity which three colour printing requires." Our author here expresses to what has for years been regarded as the weakness of trichromatics. Photographically it is a perfect system—though to say, up to the production of the negative and a few special prints. After that the falsification of the rapidly moving printing machine steps in, and, as we recently saw in "The Spectator," the chromatic renderings of coloured objects are the despair of those in whom the sense of colour exists to an acute degree. So well it will continue to be whilst the exigencies of money making demand long runs quickly executed. The first part of Von Hübl's book touches somewhat exhaustively of the undulating theory of light; of light; the theory of colour sensation; body colours and dyes; stuffs in their mixtures; and other somewhat more abstruse branches of the main subject. Running into some 50 pages, this part of the volume forms a fairly complete treatise in itself. In Part II. the author has set forth in some detail the theory and practice of three-colour printing. Forty pages are devoted to sensitisers, colours for finished print, and light filters, and in the remaining section of the book the actual practice of three colour printing receives attention. It is here, perhaps, that the photographer who would attempt the production of three colour negatives will find the book of greatest service, inasmuch as the most suitable solutions, plates, lenses, etc., are specifically mentioned—indeed, the information appears to be most minute in every detail. Very little is said of the actual block making, but printing and the inks therein used are discussed. There are many diagrams, colour charts, and other illustrations in the book, which obviously embodies so much that is valuable in connection with the theory and practice of trichromatics that it will probably be some time before it is displaced as the principal work of reference of its kind. The translation appears to be extremely well done, although here and there, if Mr. Klein will pardon us for saying so, some obscurity and ponderosity of expression are discernible. This is an appreciation rather than a criticism of a laborious piece of work the main features of which it is our immediate object to present to the reader.

SOLAR Photography.—At the recent meeting of the British Association at Cambridge Dr. W. S. Lockyer described in the cosmical physics sub-section the work done at the Solar Physics Observatory with the new instrument known as the spectro-heliograph, but recently by means of a special Government grant at a cost of £1,000. The operations consist of mono-chromatic photographs of the sun's surface and surroundings in the light of a particular element. Up to the present the calcium or K line of the spectrum has been used. Some of the results were remarkable, as showing the amazing force at work on the sun's surface. Thus a photograph taken on July 1 of this year indicated enormously rapid changes which the prominences on the limb undergo in comparatively short intervals of time. One prominence on this date in an hour's time changed from 160,000 miles in length to 96,000 miles, while its height increased from 50,000 to 60,000 miles in the same time. On July 2 an enormous prominence 192,000 miles in length grew to 216,000 miles in five hours. At the same time its height changed from 55,000 to 60,000 miles.

New Materials.

Barnet Orthochromatic Plate (Yellow Sensitive). Manufactured by Messrs. Elliott and Sons, Ltd., Barnet.

We recently drew attention to these orthochromatic plates made by Messrs. Elliott and Sons, and since then have had a fresh sample submitted to us of the "Backed" series. We find the backing that is used gives ample protection from halation, and we think that those photographers who incur the slight additional outlay will not readily turn to unprotected plates. We have had the opportunity to place these plates in the hands of Dr. Lehmann, of Munich, who has given the following report of their orthochromatic properties. For this purpose they were compared with one of the best German orthochromatic plates, which sells at about twice the price of Messrs. Elliott's manufacture: "The tests were made with a grating spectroscope of aperture 1 to 8, the width of the slit being .17 mm. and the dispersion about 12 deg. The weather was very dull. The sensitiveness yellow-green was about equal in both plates, but that of the Barnet extended rather further in both directions—i.e., into the red and violet, and with an exposure of 18 secs. the D line was visible. The sensitiveness for blue-green was greater in the Barnet plate, and from F to H it was nearly even throughout, whereas the German plate at H, between G and H, showed a pronounced maximum. (This is especially visible with 2 and 6 secs. exposure). The Barnet plate appears to be, however, much more sensitive, which I infer from the fact that it develops much more quickly. Both plates were free from grain. In practice, they should be of about the same effectiveness, but I would recommend a rather deeper screen for the Barnet, if such is used, but it should be of the paler varieties. Both plates may be used, without a screen, under circumstances, with effect."

Our experience of the Barnet plate in the camera has been most satisfying. It is rapid, easy to use, and of excellent colour sensitiveness for landscape work.

"Geka" Photographic Chemicals and Preparations. Sold by Messrs. A. E. Staley and Co., of 19, Thavies Inn, Holborn Circus, E.C.

We have received particulars and samples of the "Geka" photographic chemicals and preparations from the photo-chemical works of Dr. G. Krebs, Offenbach-on-Main. Messrs. Staley are the sole importers for Great Britain and Ireland of these productions, which include in the series we have seen practically everything chemical that the photographer finds necessary, from most efficient flash powders, etc., to mountant for the finished print. The developers are all neatly put up in glass tubes, and sample sets of "Geka" photographic chemicals, containing a pound of each of the following to make about 8 oz. solutions: "Gekaphene" "Geka" developer, carmal "Geka" developer, pyrogallol "Gekal" developer, daylight "Geka" developer, film "Geka" developer, hydrokinone "Geka" developer, brilliant "Geka" developer, triphenyl "Geka" developer, uranium "Geka" intensifier, persulfate of ammonium reducer, combined anti-hypo-hardening cartridge, vesta flashlight powder, "Geka" flashlight powder, potassium "Geka" toning bath, "Geka" acid fixing bath, "Geka" gold combined toning and fixing bath, "Geka" encaustic paste to give brilliancy to dull prints, "Geka" amylin mountant, three flash candles (two seconds), slip of touch paper for flash powders, will be sent per parcels post free on receipt of P.O. 5s. 6d.

The complete list of these preparations, containing full particulars and instructions for the use and application of the various chemicals will be sent on application to the above address. The handy form in which these productions are put on the market, and the reliability of the firm producing them, should ensure a great demand and extensive use.

RONTGEN Rays for Moscow.—According to "The Lancet" the Moscow Town Council has ordered a Rontgen-ray cabinet at a cost of £150, inclusive of dynamo, for the use of the hospital sent by the town to the Far East. This apparatus will be under the control of the manager of the hospital, and if it proves to be satisfactory more will be ordered both for the hospitals in the town and the one in the Far East.

FORTHCOMING EXHIBITIONS.

September 14-15.—Cambridge Photographic Society. Hon. Sec., T. J. Sowdon, "Sunny Side," Guest Road, Cambridge.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-Ninth Exhibition, New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

September 29.—Beverley Photographic Society. Hon. Sec., T. J. Morley.

October 15-29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

October 19-20.—Isle of Wight Photographic Society. Hon. Sec., J. Howard Burgess, 53, Pyle Street, Newport, I.W.

October 19-22.—Rotherham Photographic Society. Hon. Sec., H. C. Hemmingway, Tooker Road, Rotherham.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.

November 2-23.—Plymouth. Hon. Sec. Photographic Section, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.

November 17-18.—Braintree and Bocking Camera Club. Hon. Sec., W. H. Tilston, 81, High Street, Braintree, Essex.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Park, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issett, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Commercial & Legal Intelligence

MIDLAND COUNTIES PHOTO COMPANY.—This company has been registered with a capital of £5,000 in £1 shares, to acquire from H. Spencer the entire interest in the business carried on as the Midland Counties Photo Company, and to carry on the business of photographers, photographic artists, portrait painters, etc. The subscribers are H. Spencer; J. Knight, P. B. A. Barrington, W. Tanser, A. White, A. Dougal, and T. King.

YORK AND SON, LIMITED.—This company has been registered with a capital of £5,000 in £1 shares. Object to acquire the businesses carried on at 67, Lancaster Road, Notting Hill, W., and 30 and 32, Fryern Street, Bridgwater, as York and Son; to adopt an agreement with W. York, and to carry on the business of manufacturers, photographic publishers, optical lantern slide makers, etc. The first directors are W. York (managing director), R. York, and W. Castle; qualification one share; remuneration of managing director, £300 per annum; of other directors as fixed by the company. Registered office, 67, Lancaster Road, Notting Hill, W.

A NEAT CAPTURE.—On Tuesday the Lowestoft police made an arrest under somewhat peculiar circumstances. It appears that early in the year a young woman, named Annie Buckman, was in service at Green Place, Womersh, near Guildford, and while there was visited by a photographer, who represented himself to be employed at the Art Studio, Regent Street, London. Miss Buckman gave this gentleman an order for photographs to the value of 4s. 6d., which it was understood the Art Studio were to supply. She heard nothing further. She informed the Guildford police, who told her that they had received complaints, and believed the man was wanted at Eastbourne, Worthing, and elsewhere. The young woman eventually obtained a situation in London; recently she went to Lowestoft with her mistress, who resided at a house at Kirkley Cliff Road. On Tuesday it happened that the same man seen at Womersh called at the house on the same errand. The girl recognised him, and while other servants engaged the man in conversation, Miss Buckman fetched a policeman and the photographer was arrested and taken to Lowestoft Police Station. Supt. Shipp telegraphed to Eastbourne, as he understood from the Guildford police that they believed the man was wanted in Sussex, and the Eastbourne reply was to the effect that they would send for the man, who had been detained, and he was later in the day handed over to Detective-inspector Leonard Parker, from Eastbourne.

PHOTOGRAPHIC INDUSTRIES, LIMITED.—This company has been registered with a capital of £50,000 in £1 shares (30,000 seven per cent. cumulative preference). Object to acquire: (1) A freehold factory in Ghent, erected and fitted under the supervision of Dr. Findlay; (2) British patent, No. 5,943 of 1904, relating to the

manufacture of films, and (3) the benefit of all improvements further inventions relating to the manufacture of films discovered by the vendors (Dr. J. Findlay and Major F. E. Freeth) while they hold the position of joint managing directors, with the right to apply for and obtain patents in respect thereof in the British Dominions and foreign countries, and to carry on the business of manufacture of photographic papers, dry plates, films, cameras, and photographic apparatus, chemicals, materials, and accessories, lithographic printers of picture post-cards, and advertisements, etc. Purchased consideration, £28,500, payable as to £8,500 in cash, and as to £20,000 in ordinary shares. The signatories are: J. W. Davy, Chaloner Street, W., 250 shares; Major B. H. Gunston, 74, Gloucester Place, W., 250 shares; J. Findlay, D.Sc., 56, Selbourne Road, Ilford, 250 shares; Major F. E. Freeth, Fairholme, Malvern Road, Acoc's Green, Worcester, 250 shares; D. Tackels, 129, Chaussée Courtraï, Ghent, 250 shares; E. W. Blake, 25, Victoria Street, S.W., 250 shares; L. Tucker, 2, Queen's Road, N.W., 250 shares. Minimum cash subscription, £10,000. The number of directors is to be not less than three nor more than seven. The first are: J. W. Davy, D. Tackels; Dr. J. Findlay, Major F. E. Freeth, and Major B. Gunston. Qualification £250. Remuneration (except managing directors) £100 each per annum and £50 extra for the chairman. Remuneration of Dr. Findlay and Major F. E. Freeth (as managing directors) £2 and £350 per annum respectively. The directors (including managing directors) are to receive a further £100 in any year when 10 per cent is paid on the ordinary shares. Registered office, 25, Victoria Street, S.W.

A MEETING of the creditors of Henry Frederick Bultz, photographer of 18, Victoria Street, Paignton, was convened at the office of the official receiver, Plymouth, on Tuesday last week. Gross liabilities returned at £2,209, of which £833 9s. 5d. is expected to rank; assets £133 18s. 9d., leaving a deficiency of £699 10s. 8d. Mr. Henry Square Paignton, represented Rev. J. D. Scott, the largest creditor, £1,000. Mr. W. P. Roberts, also of Paignton, appeared for the debtor. Creditors attended. Later the debtor attended at Stonehouse Bankruptcy Court, before Mr. Registrar F. B. McCrea, for his public examination. In reply to the official receiver (Mr. T. H. Geake), the debtor said he had been carrying on business in Paignton since June 1893. He commenced with a capital of about £1,000, £400 of which was expended in the erection of a studio. The business had been profitable all along. The sole ground for his bankruptcy was an action brought against him at the last Devon Assizes. Substantially, the question was whether a sum of £450 was money lent or paid to him for services rendered. Mr. Scott, plaintiff in the action, and himself were very friendly. He took Mr. Scott about a good deal and devoted much time in teaching Mr. Scott's pupils. He helped Mr. Scott to form the school, acting as his secretary. He understood that Mr. Scott was a very wealthy man. As a result of keeping company with Mr. Scott his business suffered, and he understood that the money was given to him to make up the deficiency. Had he known that the money was only advanced he would not have done what he did. He gave his solicitors a charge upon the property to cover the costs and expenses of the witnesses at the trial. He had been in monetary difficulties before, but he had managed to pay his way. About 1901 he began borrowing from moneylenders. He had a contra account with Mr. Bowden, of Teignmouth. If Mr. Bowden said that he owed him £200 and that he (Mr. Bowden) held promissory notes he should not think it was correct; he (debtor) did not believe he owed Mr. Bowden anything. Cross-examined by Mr. Square: He was insured in the Prudential office for £100, not £50, as he inadvertently told the official receiver. He borrowed £50 on the policy and £6 he believed was still owing. His life was never insured for £2,000. His gross income was £700 a year. For the year 1902-3 his gross takings dropped about £500. No friends were holding furniture or money for him. He still asserted that he did not have the whole of the £160 in notes from Mr. Scott. Mrs. Toby, of Teignmouth, gave him £30 to pay out an execution. His present income was derived from work. Replying to Mr. Roberts, debtor said he was also a picture dealer, and the pictures he sold to Mr. Scott was in the ordinary way of business. Replying to the official receiver, the debtor said a certain amount of the furniture belonged to his wife, while other goods were brought to the house by his wife's father and mother, who reside with them. The examination was closed.

News and Notes.

have received the syllabus of lectures, etc., for the forthcoming season from the Bowes Park and District Photographic Society. It contains the promise of a good series of interesting lectures.

Big Photograph.—At the exhibition of the R.P.S., Mr. W. H. of Talbot Lodge Studios, Reading, will exhibit an enlargement of nine feet long of a Royal group taken at Wellington College during the King's visit recently.

We would remind our readers that the entries for the Newbury Photographic Exhibition close on Thursday, September 1st. The nature of the prizes, the varied and comprehensive nature of the competitions, the names of the judges, and the high-class nature of this exhibition generally should be noted. Mr. E. J. Forster, Hon. Sec., Guildhall Club, Newbury, will gladly send schedules, etc., immediately on application.

An instructive series of lantern slides illustrating waves and other forms of the atmosphere, hydrosphere, and lithosphere has been collected by Dr. Vaughan Cornish for Messrs. Newton and Co. The collection includes the most interesting pictures shown by Cornish at the Royal Geographical Society and elsewhere, and descriptive notes which have been prepared for the slides direct to the chief points of interest.

A CROWDED audience at the Drill Hall, Bridport, was witnessing a show of animated pictures on Monday night when one of the films burnt, and the hall was suddenly lit up by a blaze of fire. The proprietor and a lady vocalist begged the people to keep quiet, but as the hall was in darkness many persons started to rush out. Fortunately excitement was soon quelled, and after the burning film had been removed out of the hall the entertainment was proceeded with.

To understand that Messrs. Watson and Sons, of 313, High Street, W.C., are now able to supply their "Argus" reflex camera of self-plate size, the dimensions over all projections being as follows: height 7 by 7½ in., and the weight of the camera 5½ lb. This compares favourably with those of other reflex cameras taking this size of plate. The cost of the camera, with three dark slides, has been fixed at 10gs., subject to a cash discount of 5 per cent.

BEVERLEY Photographic Society.—An exhibition in connection with this society will take place on Thursday, September 29 next. There is only one class in the open section, and that is for landscape, nature, and architecture. Any number of prints may be sent in. Entries close on Saturday, September 24, and entry forms can be obtained from T. J. Morley, hon. secretary, Beverley Photographic Society, Beverley.

BOARDMAN'S Electric Arc Lamps.—With the approach of the autumn season special interest attaches to those lighting systems which enable the photographer to work by artificial means. We have received the latest list of the Boardman Electric Patents Co., Limited, of 10, Southwark Bridge Road, London, S.E. This deals with electric arc lamps constructed for portraiture and other photographic purposes. It should be in the hands of all our readers desirous of familiarising themselves with the latest devices in these directions.

MANY of our readers, and in particular those of them who are acquainted with the life and work of the late Mr. Leon Warnerke, whose contributions to photographic knowledge earned him many thanks, and the thanks of innumerable photographers may be interested to know that his daughter, Miss Maria Léon, of 30, Regent Street, London, S.W., recently opened a studio at that address. Miss Léon devotes herself to a general practice, including portraiture, architectural photography, the reproduction of paintings and commercial specimens, printing for amateurs and the trade, developing and engraving, and the giving of lessons. We have seen specimens of her work, and can pronounce them as evidencing the possession of great artistic and technical ability. It is a great gratification to us to perceive in the daughter of the late Mr. Warnerke an accomplished artist in the stress of photography, and we wish her the utmost success in her enterprise.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—I am sorry that you have announced "that your columns are closed on the subject of spirit photography," but I claim your indulgence, especially concerning "X's" remarks about the late Traill Taylor. I cannot allow his revered memory to be libelled in such a manner. I have yet to learn that an attack of dysentery (which was the cause of death) should in any way impair his intellectual years before. I was one of several who saw him depart for America, and was the last he spoke to on the platform at Waterloo. His words were, "Look here, Henderson, I will have my Christmas dinner in England."

Apropos of what some may think a recantation, I may mention that we had an understanding that whoever passed away first (if spiritualism was a truth) would give certain signs, which up to the present moment have not been fulfilled. Does this not tell its own tale? Does it show a falling off of mental power? I have to thank "X" for his complimentary remarks about myself. When he has had over fifty years' photographic experience and nearly forty years' experimental investigation in so-called spiritualism his opinion may be equal to and worth as much as that of yours truly,

A. L. HENDERSON.

Westmoor Hall, Brimsdown, Ponders End, Middlesex.

August 26th, 1904.

[We well remember that our late friend and predecessor, Mr. Traill Taylor, was in excellent health and spirits at the time of his departure for America. And now, to the discussion of psychic photography in these columns we must courteously but firmly apply the closure.—Eds. "B.J.P."]

THE FUTURE OF PROFESSIONAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—When reading the article in your issue of August 12, re the future of photography, it occurred to me that perhaps a few remarks from one who has experienced both sides of the matter, employer and employé, might be acceptable. While agreeing with your correspondent on most points, I think the question presents phases other than those mentioned, and I am inclined to agree with the remark in your appended footnote. Mediocrity certainly does abound, and in a more far-reaching sense than is generally recognised; but I do not think that this is the direct cause of the cutting of salaries, although undoubtedly it does not help to mend matters. The introduction of simplified methods should in my opinion have resulted in the quality of work rising to a far higher standard than it has done, both technical and artistic; but instead of this being the case we find that the productions of some of the good wet-plate workers not only compare very favourably with our present examples of photography, but in many cases excel them. Why is this?

My theory is this. The manipulation of the collodion, silver bath, and other similar processes required really clever men to work them in anything like perfection, and consequently they devoted themselves thoroughly to the overcoming of difficulties and the production of first-class results; whereas now it has all been made so easy that very few trouble to go beyond a certain point, preferring to benefit by the brains of the pioneers of photography, and are either too ignorant, lazy, or egotistical to see their glaring defects and endeavour to attain to greater perfection, which would increase their market value besides being more creditable to themselves. This applies not only to the inferior firms, but in a less marked degree to some of our best houses, where, even if, as in many cases, the work is really good in technique, it is sadly lacking in artistic merit, the sitter being unmistakably, and often crudely, posed, and wearing a distinctly photographic expression. There are, of course, sitters of whom it is impossible to make anything really picturesque or even natural, but I am stating the matter in a general sense.

I have usually found that by tactfully diverting the attention of nervous and self-conscious sitters from what they regard as an ordeal, by genial conversation while posing, focussing, etc., a much more natural and pleasing effect can be obtained, and in some cases when conditions of light have been favourable, I have exposed the plates during conversation quite unknown to the sitter; and although to do this is by means the easy matter it might appear if everything is to be correct, the results have fully repaid me for the extra trouble and patience required. Art, as I understand it, lies in concealing the art under an appearance of natural simplicity; but it would appear that the average operator's idea of it consists of obtaining some unusual effect, at no matter what loss of ease, grace, and suitability to the subject. It seems to me that the really good men are only those who take a deep and genuine interest in their work for love of it, and not only for pecuniary benefit; but these are very much in the minority. It has often been a matter of wonder to me that firms who require first-class ability should offer so very little monetary encouragement to assistants, and when we consider that many third-rate operators get salaries of £2 and commission, which amounts to very nearly as much as that paid by good houses, can we be surprised that mediocrity does abound, because these men have no immaculate appearance to maintain, and their work is not nearly so particular?

Photography has, of course, become cheapened by popularity and competition, and, like everything else, the lowering of prices, and the springing up of new studios means less turnover for principals, and consequent cutting of expenses, and the crowded state of the labour market affords plenty of scope for the reducing of wages. Then, again, the expense of carrying on a business is far greater than many people (especially assistants) understand. Rent is enormous in the best business parts of any of our large towns; then there are rates, light, material, printing, and salaries, besides small every-day expenses, all to be paid before the proprietor gets a penny for himself, and considering the state of business in England during the last few years, the wonder is that some master-men get a living at all. Still, with all this there are firms who go to needless extremes in the cutting of salaries, and in some cases it would seem that the more noted the firm the greater the evil; and if, after all, the state of business does not allow of a moderately good salary being paid, there is still the alternative method of adding a commission to the present salaries, which would only mean increase of expenditure with increase of business. I feel convinced that if first-class firms were to consider their assistants a little more, the work would in many cases improve, for be the employés ever so philanthropic, they are inclined to work with far greater interest if by so doing they are benefiting themselves as well as the firm, and especially in cases where the business is left almost entirely to a managing operator, who can, without doubt, influence business by the unvarying production of really good work, and by favourably impressing clients with politeness, suavity of manner, and an apparent interest in their whims and fancies. He can also during conversation quite casually draw their attention to some more expensive production, and often without any undue persuasion can obtain orders which otherwise would never be given, though this requires experience and tact not to overstep the mark. I am inclined to think that there are still firms who would be willing to pay a very fair salary if they could only obtain really first-class ability, but as I have said, clever men in photography are conspicuous by their absence.

One of the best evidences we have of this fact lies in an advertisement in the *BRITISH JOURNAL OF PHOTOGRAPHY* a short time back, when a leading firm were wanting a managing operator, and after the advertisement appearing for three or four weeks, it stopped for a time, during which we may suppose an applicant was being tried, and then appeared again for a further period of three weeks; and this when business is almost at a standstill in England. Surely the firm should have had no difficulty in securing a first-class worker in a week.

Again, a noted firm also advertised very lately for a retoucher, offering £2 5s. per week, which is good as salaries go now, and later on again offering £2 10s., and still the advertisement appeared for several consecutive weeks, by which it would seem that they found it difficult to get a competent man. The market may be crowded, but scarcely it would appear with really genuine talent. It would be interesting to have one or two opinions from heads of first-class houses on the subject. I fear I have left retouchers, printers, receptionists,

etc., out in the cold in this letter, but the same state of inferiority seems to abound here, though perhaps in a less marked degree with operators, and the remedy, I fancy, is more difficult to find than they are glutting the market to a greater extent. It would seem the only improvement that can be suggested is the improvement of one's own personal ability. There is no standard so high but might be excelled, no knowledge so great but might be greater, and the more we learn, the more we can realise our own ignorance, and the greater truth of the words attributed to Socrates, "I know that I know nothing."—Yours faithfully,

M. ARNETT

"Clifton," Glenelg Road, Brixton, S.W.

August 23, 1904.

AUSTRALIAN TRADE MARKS.

To the Editors.

Gentlemen. Through the courtesy of an Australian Member of Parliament we have received an advance copy of the new Trade Marks Bill for an Act to cover the Six States forming the Commonwealth, namely, New South Wales, Victoria, Queensland, South Australia, West Australia, and Tasmania.

The Bill, which has just been introduced into the Senate, is a complement of the Fraudulent Marks Bill. The new Bill states at outset that, subject to certain limitations imposed, the common law of England relating to trade marks shall apply throughout the Commonwealth, and the States Trade Marks Acts cease to operate further than that the State Trade Marks Act under which a trade mark registered shall continue to apply to that trade mark, so long as registration under that Act remains in force. The registration of a trade mark under a State Act is to cease either at the expiration of fourteen years from the commencement of the new Act, or at any time when it first becomes liable to removal from the Register, whichever event first happens.

Trade marks already registered under State Acts may be federally registered. Where, however, the trade mark, or a nearly identical trade mark, is common to the trade in another State, it may be registered with an exception as to that State. The administrative sections of the Bill make the Minister of Customs the political head of the administration, with a Registrar of Trade Marks as executive officer. To the Minister and his subordinate all functions performed by State Ministers and officers in relation to trade marks, together with all records, are to be transferred. The essential particulars of a registrable trade mark are practically identical with the British. The additional matter which may be added to the essential particulars registered is limited to letters, words, or figures. No trade mark may contain the word Royal or a representation of the Royal Arms or Crown, the national flag of Great Britain, or that of the Commonwealth, or of any Australian State. Elaborate precautions for protecting owners against infringement are embodied in the Bill.

International arrangements for the protection of trade marks are provided for in the final clauses of the Bill. The protection afforded must, it is indicated, be reciprocal. If a foreign country is shown by an order of the Imperial Executive Council to be prepared to protect British trade marks in return for protection being given to trade marks, then the Commonwealth Government may enter into a similar arrangement.—Yours truly,

W. P. THOMPSON AND CO.,

Chartered Patent Agents.

6, Lord Street, Liverpool, August 23, 1904.

TINTERN ABBEY.

To the Editors.

Gentlemen. Every visitor to the Wye Valley has, of course, seen the ruins of the beautiful Abbey of Tintern, and everyone with a camera has, it goes without saying, photographed them from different points of view. For some time past these ruins, which, with the last adjoining, were bought by the Crown authorities from the Duke of Beaufort, have been in a rapid state of decay and some portions are in danger of falling. They are now being repaired. According to a writer to the "Standard," the eastern end of the nave is now covered by a forest of scaffolding. Therefore photographers who intend visiting the ruins this autumn will know what they will find. The writer says that the scaffolding has been erected to permit of supports be-

ced to the slender central shaft of the big east window, which some time past has been in danger of falling. The work now in progress includes the strengthening of the mullions of several of the windows of the nave and the pointing of most of the exterior. The preservation scheme includes the fastening of dangerous stones and removal of others. Of course, ruins of the type of Tintern Abbey need looking after, and at times repair to keep them from falling to a state of further decay; but it is to be hoped that nothing will be done in the way of repair that will at all alter their original character. Probably Tintern Abbey is the most photographed object of the whole of the Wye Valley, and there are hundreds of photographs that will testify as to whether its repairs have militated against beauty.—I am, yours, etc.,

A SOMERSETSHIRE PHOTOGRAPHER.

August 27th, 1904.

"SEIDLITZ" P.O.P.

"To the Editors.

Gentlemen.—There are several errors in my paper. It is usual to blame the printer; he is a merrie dog—clever withal, and must have his little joke. How he contrived to alter the type after it had passed the reader is beyond me; perhaps some day I shall understand. However, I accept the whole blame myself. It makes no use for further communication.

Page 745, col. 2, line 15, "work" should be "soak." Nine lines later, "swandown, calico" should be "swansdown-calico." The leached is more serviceable than the bleached, and cheaper, at 7d. or 8d. a yard does very well. Emulsion will not go through the highest qualities without pressure. And in the following, for "nitrate of silver" read "citrate of silver." The other mistakes are of no consequence.—Yours truly,

ALF. J. BROWN.

August 29, 1904.

SHEFFIELD Photographic Society.—The prospectus and entry form for the forthcoming exhibition of this society is to hand. It is printed on the outside with a representation of the society's plaque which appears to be not only good in design, but original in conception, and embodies the idea of the industries of Sheffield. The latest date for entries is November 5, and the judges will be Messrs. Alex. Keighley, Frank M. Sutcliffe, and C. Barrow Keene. There are six open classes, and full particulars can be obtained in the Hon. Sec., J. W. Charlesworth, 1, Joshua Road, Sheffield.

PHOTOLINOL enlargements as supplied by Photolinol, Ltd., of 10, Holland Park Avenue, London, W., should prove popular. This material, although requiring only the same treatment as bromide paper for the production of a photograph, has the great advantage of durability, the fabric being practically indestructible, waterproof, and impervious to the action of the sun. It can be rolled, stretched, or stretched, without the slightest injury to the photograph; it adapts itself to a legion of novel uses, its chief feature being high translucency. The company manufactures and prepares the material in cut sizes, in rolls (and on stretchers of standard measurements), in any length, and up to 10 ft. wide. They also produce their works, Chiswick Hall, W., enlargements to order up to 10 ft. wide. For an extremely nominal sum enlargements up to 16 in. on this new bromide linen will be supplied complete with etcher from customer's own negatives. As a paying line for the professional photographer these enlargements, which should be as permanent as any photographic process extant, deserve attention, in fact, also, that the base is linen offers endless opportunities for working up or painting in solid oils. The Photolinol Company will, however, undertake this part of the work, and also copying and original studio work. They are extending their facilities in this direction in fitting out their studios and galleries at Holland Park Avenue in the most approved and up-to-date style, and will shortly have ready a complete stage with proscenium and scenery for the mounting and photographing of actors and actresses amid "natural" surroundings. Their enterprise is to be commended, and photographers should apply to the company for the latest price lists and particulars of its productions.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- C. Foster, Promenade, Port St. Mary, Isle-of-Man. Two Photographs of Bathers in Port Erin Bay.
- G. C. Morrell, 17, Alexandra Road, Morecambe, W.E. Photograph of finished Heysham Docks. Photograph of High Tide looking East at Morecambe, W.E.
- J. H. Smith, Waller Hill, Skipton. Photograph of "General" Booth.
- C. A. Brett, 1, Avenue Road, Hampton, Middlesex. Photograph of Colonel H. Bott.
- J. Bullock, 37, Clipstone Street, Leicester. Photograph of a Lift at Foxton, near Market Harborough.
- A. E. Seaman, 13, High Street, Chesterfield. Photograph of Mr. W. G. Grace and others Playing Cricket.

E. WHEELER.—The article referred to was held over just before the publication of the Almanac.

A. CLARKE.—If you will carefully read the paragraph in question again, you will perceive that coloured postcards are referred to.

J. W. DEBENHAM.—We believe the light may be seen at the British Westinghouse Company's offices, Norfolk Street, Strand. Kindly note that we do not undertake to answer letters by post.

RESTRAINER.—H. B. C. asks: "What acts as a restrainer to the pyro soda developer? I have tried bromide, which is most effectual with pyro ammonia, but find it does not appear to influence the pyro soda developer."—In reply: Bromide of potassium acts with pyro soda in the same way as with pyro ammonia. Have you not made a mistake somewhere?

STAINS FOR STUDIO FLOOR.—PROFESSIONAL says: "I wish to stain the floor of my studio a rich dark colour that will wear well. Can you give me a formula for such a stain? I should prefer walnut colour."—In reply: A reliable walnut stain can be prepared as follows: Take water 1 quart, washing soda 1½oz., vandyke brown 2½oz., bicarbonate of potash 4oz. Boil for ten minutes, and apply with a brush. This stain may be used either hot or cold.

COPYRIGHT.—DONALD says: "Recently I photographed a gentleman's residence. The photograph was taken from a public footpath. I have since published it in postcard form. The gentleman objects, and orders me to cease from selling any further copies. The photograph was a speculation on my part, and the sole copyright belongs to me. (1) Can you tell me if he can stop me selling further copies, (2) or compel me to destroy those I already have?"—In reply: If the photograph was taken from a public path the owner of the house cannot prevent the sale of the picture.

DISCOLOURED PRINT.—POSTCARD asks: "Can you tell me the cause of the back of enclosed postcard being discoloured? The cards are self-toning, and are fixed in a bath of hypo, 1 to 5. The discoloration begins to show about five minutes after prints are washing. I have tried all sorts of dodges, but can only get rid of it one way, that is, washing cards before fixing; but that alters the tone of them to a red instead of the nice brown of enclosed card. I shall be pleased to have your help. I may say that the makers' instructions are followed implicitly."—In reply: As we do not know how the cards are prepared, we cannot say. Why not write to the makers, and send them an example of your trouble?

VARNISH FOR PRINTS.—VELOX asks for a reliable varnish for protecting the surface of large bromide and other prints.—In reply: The following formula should be employed:—Borax 10grs., pale yellow shellac 30grs., carbonate of soda 5grs., glycerine 15ml., water 1oz. The addition of alcohol will improve this, and in this case it is better to use only ½oz. of water, boil, and then, when cool, add the alcohol, allow to stand for two or three days and filter. This is always a difficult thing to clear, and the best thing to do is to add about 5 per cent. of powdered pumice-stone and snake well and allow to settle; the pumice merely carries the floating particles of insoluble resin to the bottom.

OPINION WANTED.—MEDIUM writes: "1. Enclosed please find a few prints of my retouching, and I should be glad if you would kindly criticise them for me, and let me know if the work is worth 30s. per week as retoucher and general, considering the state of the labour market and things generally. 2. Can you let me know the price of the two following books: 'Artistic Lighting' and 'The Studio, and what to do in it'?"—In reply: 1. The work is poor, and we think it would not command more than the salary mentioned, if so much, considering the present state of the labour market. 2. The price of the works is 2s. 6d. each. We are continually saying that we do not answer correspondents by post.

SOLAR PRINTS.—A. GRIKSEN (Cape Town) writes: "Please give me the process of making solar prints, from the salting and sensitising of the paper to the fixing of the prints, or if there is any book giving the information please give name of same and where to be had."—In reply: To give such working instructions as would of any practical use would take up a page of the JOURNAL, and, moreover, the information would be of no interest to the general body of our readers, who, here in England employ one or other of the commercial bromide papers. All the earlier works on photography give the method of working. Abney's "Treatise on photography" is a good book; it may be had through any stock dealer.

BACKGROUNDS.—BACKGROUND says: "Will 'you kindly publish formulae for painting backgrounds in flatted oil and distemper? Also please state how canvas must be prepared in each case, and any particulars which you may consider necessary for guidance of an amateur."—In reply: Stretch unbleached sheeting on a frame and then size it with the ordinary size of the oil shops. Then, for distemper, mix together whiting, drop black, with a little Venetian red (to warm the tint) to the colour desired, with a little water; next add sufficient size to form a tremulous jelly when cold. Apply, cold, with a soft whitewash brush. For flating, size as before, and then paint with ordinary paint the colour desired. When dry make up flating colour with turpentine only, then add about a third of its bulk of Japanese gold size. Apply with a large painter's brush and stipple over the surface with a dry brush as it is laid on. There is no book published on the subject.

FLEXIBLE SUPPORT FOR CARBON PRINTING.—J. W. R. says: "Will you please tell me how to prepare flexible supports for carbon printing?"—In reply: The flexible support used in carbon printing is paper coated with an aqueous solution of shellac, made as under: White shellac 5oz., borax 1oz., water 20oz. Place the water and borax in a saucepan or similar vessel, and put on the fire. When the borax is dissolved, add the lac broken up into small pieces, and boil, stirring the while, until the lac is dissolved. Continue the boiling for three or four minutes, and then allow to cool. Strain through fine muslin, or filter through paper. Dilute with water according to the coating required on the paper, and pour into a flat dish. Float the paper on this for two or three minutes, and hang up to dry. A little glycerine added to the above—say half an ounce—will give greater flexibility to the coating than it would have without this addition. We may mention that the commercial flexible support usually has a substratum of insoluble gelatine before the lac solution is applied.

AMIDOL.—THE PHOTO DEVELOPMENT SYNDICATE write as follows: "Some three weeks ago I had occasion to mix a large quantity

of amidol—some 8oz.—and the weather being very hot at the time, I was perspiring very freely, and I think in consequence of having passed my hands over my face I have contracted amidol poisoning, which has had the effect of causing severe irritation of the eyelids, on the face, and a recurrent appearance of tiny sago-like lumps on the skin between some of my fingers. I have consulted my doctor, but unfortunately appears to be unable to give me any relief; but I have been informed that you gave a treatise on this poisoning, in one of your back numbers. In any case, I should be extremely grateful if you could give me any advice in the matter."—In reply: In our experience we have found no ill effects from use of amidol, though many have done so from metal which possibly, the article suggested applied. Perhaps a reader may help our correspondent? No such article appeared in our pages.

Patent News.

The following applications for Patents were made between August 15th and August 20th, 1904:—

- Printing Apparatus.—No. 17,695. "An improved apparatus for printing photographs." Complete specification. Frederick John Seaman.
- Enamelling Photographs.—No. 17,986. "Improved process for enamelling engravings, photographs, and the like." Leon Thines.
- Pocket Camera.—No. 18,019. "Improved pocket or folding camera." Complete specification. Adolph Richard Lange.
- Shutters.—No. 18,057. "Improvements in photographic shutters." Abraham Kershaw.
- Lighting.—No. 18,099. "Improved method of lighting for photographic purposes." Complete specification. Eduard Mertens.
- Backgrounds.—No. 18,102. "Improvements connected with photographic backgrounds." George Rutter.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to, where necessary, the year's advances in theory and practice will be recorded.

** The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis (medallist of the Royal Photographic Society's Exhibition, 1903).

** IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that this year the entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA.

A New Use for Celluloid. Detective Reilly, of the Mount Vernon Police, New York, owes it to a thick turn-down celluloid collar that he is at this moment not down among the dead men but very much alive. In a struggle with a highwayman the latter drew a revolver and shot the officer at short range, the bullet being stopped by the collar. In the confusion of the moment the man who fired the shot escaped, although Reilly was quick to recover from the blow, and pursued his man. This indicates a new use for celluloid in the provision of light armour which a man engaged in dangerous enterprises might wear without inconvenience beneath his coat. When the world was far more sentimental than it is now various stories were current of soldiers who had been through the heat of battle and found afterwards a bullet embedded in the bible or testament worn in a breast pocket given by the warrior's mother. There were so many of these tales flying about that one was apt to suspect that bullets had been fired into bibles for the set purpose of giving colour to them. The story will henceforward take a new version, and we shall read how Private Smith, having a packet of So-and-So's celluloid films in his breast pocket, found that a bullet had been caught in their coils, and that his life had been thus saved. They would probably be stated to have been developed films, so that the uninitiated could better understand what is meant by a "hard" negative.

* * *

Comic Art.

Just as a child must have its toys, so, it would seem, must those of older growth have something of a frivolous nature with which to forget for a time the cares of existence. Hence we have to suffer from the inanities of the sentimental and serio-comic song, and the publication of pictorial jokes of that feeble sort which can be purchased for about a halfpenny a hundred if one cares to invest in the latest issue of "Flimsybits" or "Boozybits," or whatever the name of the illustrated journal happens to be. We ourselves take a sort of fatherly interest in these publications, for we know well enough that they are born of photography. Without the process block they would have been impossible. That they bring delight to many is unquestionable, or they could not live; and we have often wondered what kind of mental organisation is that which can be roused to laughter by these pictorial buffooneries. The most recent of the family is a journal printed in colours. The blocks are not of the genuine trichromatic kind, but are of the more ancient type, consisting of an outline printed in black, filled in by subsequent impressions by tints of a very crude kind. One curious thing about them is that they represent a revival of the old comic toy lantern slide pictures. Some of us are old enough to remember the particular type of toy lantern to

which we refer. A tin arrangement, about seven inches high, with a spectacle lens, and a most evil-smelling oil lamp, accompanied by a box of glass slides, upon which the pictures were painted in varnish colours. It is interesting to find these pictorial monstrosities cropping up after so many years in another form.

* * *

A Beauty Show.

Bethnal Green and Whitechapel are not places which one usually associates with things beautiful and esthetic, and this shows how wrong we are likely to be when we speak merely from hearsay and not from personal knowledge. There is so much beauty hidden away in those two East End parishes that a beauty show has been held, just as they might hold a chrysanthemum show in Japan, or a hop show in Kent. And it is said that the judges had a most difficult task to perform, seeing that a bevy of blushing damsels came up as competitors for the prizes offered. It was the judgment of Paris over again, only that there were more than three competitors, and the first prize was a sewing machine, which would obviously have been quite useless to the trio of fair ones who have formed the subjects of so many classical pictures. We trust that the East End photographers were not slow to take advantage of this rare occurrence, and that we shall have an opportunity of judging ourselves of the particular type of beauty which commends itself to a Whitechapel jury. It must certainly have been somewhat embarrassing, both to judge and judged to hear a plaintive cry from the gallery when the ladies first tripped upon the platform, "Call this a beauty show, guv'nor?" but, of course we must not look in the East for that delicacy of feeling which distinguishes the West. Let us hope that pictures of the prize winners will adorn many a packet of tea, or other necessary comestible, or at any rate that the photographs will appear in the form of pictorial postcards. The opportunity of securing photographic records of the beautiful should never be missed.

* * *

Sustaining Interest in Work.

The photographer is not exempt from the operation of the natural law of action and reaction. Strong interest in work comes in bursts, followed by the reaction of temporary periods of lessened, if not total, lack of interest. In as far as this is generally the method of Nature in attaining her results, it would be unwise to attempt to alter it by what we may presume, on the face of it, to be a better method. Still, Nature will allow of modification within the strict compass of the action of her law. It is quite possible, for instance, to discipline oneself to a uniform method and practice of work by which the occasional burst of enthusiasm is toned down, and the corresponding period of reaction toned up. But such discipline is not tempting, nor is the uniform grey—however good a grey—of the result so pleasing as are the dashes of vivid colour, although alternating with the drab of many a stretch of the mud, of failure, or less carefully disciplined work. Whilst accepting the unquestionably higher worth and better results of the spirited effort of the more occasional burst of enthusiasm, we contend that it is possible and wise to modify to the worker's advantage the inevitable reaction. We wish we could believe the reaction to be avoidable, or possible of reduction in amount; but there is no getting behind the natural law, that "for every action there is a corresponding reaction, equal in amount, and opposite in kind." Fortunately, it is not also ordained that the reaction need necessarily come in one large amount, such as the specific form of the force which produced it. It is such a modification in the incidence

of reaction as to spread it out more, that we would, from personal experience, recommend wherever possible to other workers.

* * *

Deferred Development.

The suggestion is offered the moment readily at the present time, when thinking of the large number of holiday exposures that must be awaiting development. Taking the picture is one thing, developing it another. The accessories of sunshine, breeziness, change of scene, high spirits, and agreeable companionship of exposures, are very different to the gloom, the stuffiness, the loneliness, and the tediousness of the dark room and development. A dozen exposures may have taken up two or three days; there will be an effort to develop them in as many, or less, a number of hours. The result will be a weariness of the flesh, due in greatest measure to a less wise method of working, but attributed, and to its prejudice, to photography in general. The remedy is to spread the developing of the exposed summer plates and films over a longer period. It would be wise to allow a little time to pass after the holiday even before starting the development. Let the holiday maker wait a while, until he shall have shaken down a bit. As a rule, after a holiday some arrears of work have to be pulled up, friends seen, and so forth, and it is a mistake to be working in the dark room against time, and the consciousness of there being other duties unfulfilled outside it. Even if there be full leisure, there is yet a certain holiday fatigue of mind existing, that it would be wise to allow to wear off first. Arguing from the point of view of being an ordinary, average photographer, and an average man, we hold that at the very best there is an inevitable waning of interest, and a weariness of the work, after the careful developing of not more than six negatives, and that if work be continued against the grain after this, it is certain to suffer. As exposed plates will not be a scrap the worse for having been kept undeveloped for at least three months, there is no reason against, but every reason for, spreading development over that length of time. There are plenty of dull wintry evenings coming along when work in the dark room for a couple of hours would be an agreeable relief to reading or twiddling of thumbs.

* * *

Fatal Curiosity.

There is certainly opposed to this method the desire to see as soon as possible how the holiday efforts have turned out, but the counterbalancing consciousness that the best is being made of them by gradual working, should prove a sufficient compensation. The recalled emotions that induced the taking of the pictures will also prove the fresher and stronger from the fallow in which the mind has lain in the meantime. The conditions of working in winter may also be advanced against the suggestion. If the dark room be the coal cellar, the strength of the argument is admitted. It is too cold for comfort, and the space is more cramped from the winter's supply of coal. But if any other room, it will be cold. There is no reason why it should; why development may not be carried out with perfect safety in an ordinary room with a fire in it, and the plates taken out for washing into the scullery or bathroom. A flaming, flashing fire is, of course, out of the question, but one damped down with a shovelful or two of wet slack is not, with a large screen—of brown paper, in the absence of the orthodox one with the stork in the corner—in its front. With one's back turned towards such a protecting fire, and an easy fitting cover to the developing dish, there need be no fear of damage to most plates, short of extremely sensitive ones—which no photo-

grapher of any experience uses, except for very exceptional work. The development which we have ourselves found best under such circumstances—rarely making note, it must be confessed, of exposures—is that with weakened pyro-soda (with a restraining few drops of a 10 per cent. solution of bromide), strengthened as development proceeds, or otherwise modified as the necessity for a little special treatment may be indicated as the picture unfolds itself, and its details are recognised. The same procedure will apply not merely at holiday, but at all times. A man should not force himself against his inclinations into the dark room by an over anxiety to see how his work has turned out, but take mental photographic rest, and allow the developing mood a chance to assert itself interestedly and at leisure. The plates will be all right, the work will certainly be better, and interest in photography generally be sustained at a more uniform and comfortable pitch.

* * *

The Telescope in War. The telescope has always been regarded as a very necessary part of a naval man's outfit, and this is so well understood that any landsman who wishes to be mistaken for a "sea-dog" invariably invests in a telescope so that as he traverses the marine parade he can take it from under his arm at frequent intervals and with it sweep the horizon. But the soldier has ignored this aid to vision, unless, indeed, he has despised it. In a battle picture the Commander-in-Chief is sometimes represented looking through a telescope, but no one ever dreamed of his subordinates indulging in such a rarity. But times have changed since the old battle pictures were painted, and now there is a call for telescopes in our army. The matter came up last Session in the House of Lords during a discussion on the armament and position of the Yeomanry, and the ball was opened by the Earl of Wemyss, who asserted that the great want in the late Boer war was scouts who knew how to scout and men who knew how to use the telescope. He further stated that after the slaughter of the Highlanders at Magersfontein a general wrote to the Astronomer at the Cape, and said: "For God's sake send me as many telescopes as you can." Earl Roberts said that he had always used a telescope, and he thought it would be a great advantage if it was more generally used by officers. Lord Lovat also spoke in favour of the instrument, but advocated the abolition of "the obsolete telescope" of the War Office. It must not be taken from this that the War Office only possesses one telescope, but that the type which it has adopted is now out of date. It would not be difficult, to anyone who has a fair knowledge of the episodes of recent wars, to point to several instances in which the intelligent use of a telescope would have saved a disaster to the British arms. A good telescope and a commanding eminence from which to point it would afford most valuable information as to the presence or absence of an enemy for a radius of many miles, and in future wars possibly both of these desiderata will be forthcoming. There is no difficulty about the first, and if recent reports be true there will be little about the last. Mr. Cody has invented a man-lifting kite which has been the subject of experiment at Aldershot with a view to testing its usefulness for observation purposes in war time. It will pack up into small compass, and can be flown in a heavy wind which would render a balloon useless. So that in future campaigns, instead of the cumbersome balloon and its accompanying gas cylinders, we shall have a simple form of kite at the end of a steel wire, with a man hanging from it in a cage armed with a telescope. Of course, he will have a camera fitted with a telephoto lens as well. Nor will the apparatus be confined to military purposes. The bold men who swing over precipices and climb high trees for the laudable purpose of

photographing a birds' nest will, of course, take to the Cody kite, and the same implement will be employed for photographing inaccessible details of architecture in many old buildings. The snapshotting hooligan will possibly quickly see the advantage of the kite as a means of obtaining views of domestic interiors so far as they are commanded by top windows. It may be that the kite will open up many new spheres of action for the photographer, and will prove quite as useful to him as it promises to be to the military man.

* * *

Polar Photography. Possibly before these lines appear in print the members of the British Expedition to the Antarctic regions will have reached home and received the congratulations of their friends and fellow-countrymen, after their three years' absence upon one of the most important explorations ever undertaken. We may reasonably hope that the voyageurs will bring home with them a large collection of photographs so that we may all see what the scenery is like of the inhospitable regions where they have spent so long a time. Three years is a long period over which to spread the consumption of a stock of plates, but plates, as we all know, can, under favourable conditions, be kept in good condition longer than that. It is the warm, clammy air of the tropics that plays such havoc with gelatine; nor can we expect that a state of the atmosphere which will cover a pair of boots with a coating of grey mould in a single night can be very good for photographic plates which were once "dry." In the cold of the Antarctic zone plates should keep very well indeed, provided that they were originally properly packed, and even were it otherwise it would not be an impossible thing for men used to scientific methods to make a batch of plates for themselves should the original supply get spoilt or run short. Such experimental work would, in fact, be a relief to the monotony of a polar winter. Plate-coating on shipboard is not an occupation to be recommended as a rule, for the motion of the vessel would interfere rather with the coating operation, but when the water around is congealed into ice, and we have to deal with "a painted ship upon a painted ocean," everything must be so still that its cabin, with nothing to illuminate its darkness but an occasional gleam of the Aurora Australis, must be quite an ideal place for photographic laboratory operations. We may therefore hope that no lack of plates prevented the expedition bringing home with it quite a gallery of pictures. But there is one picture which will not be found in the collection, much as it would interest geographers to possess one. In the year 1841 Captain Dougherty reported the discovery of an island in a certain part of the Pacific where no island was marked upon the charts. Eighteen years later Captain Keates reported that he had sighted an island in the same place, that is, about half way between New Zealand and the south of South America. It was said to have a rocky structure, to be about seven miles long, with a glacier in the central portion which had an altitude of about three hundred feet. Nothing more was known of Dougherty Island, and for some reason or other no man had landed there. The Antarctic Expedition looked out for the land of Dougherty, but found it not. They, in fact, sailed over the place where it was supposed to be, and instead of finding any trace of it, their soundings revealed a depth of nearly three miles! Whether the island has been destroyed by some volcanic eruption, or whether its observers were misled by the appearance of an iceberg, and the island was a myth, will probably never be known. If either of its sponsors had taken a photograph of the place it would have been possible to test the iceberg theory. As it is, Dougherty Island must be erased from the maps, although its alleged existence will doubtless be utilised by one of our wonder-loving novelists.

SILVER PRINTS: ANCIENT AND MODERN.

It will be remembered that in concluding an article (see page 724 *ante*) on the stability of the prints made in the early days of our art-science, as compared with those made at the present time, we intimated that we might recur to the subject and point out the different conditions under which the prints were made then and now. Since that article appeared many have been anxious to learn how the prints that have proved permanent for so long a time were made, and whether the conditions then obtaining cannot be applied to the present-day system of working with the object of securing greater stability in our silver pictures. This shows that at least some workers are really desirous of obtaining results that will prove more permanent than the majority of modern ones do. Very many who have only entered the ranks of photography during the last few years, and whose practice has been confined entirely to the working of emulsion plates and papers, have really very little idea of the older printing methods—the plain salted and albuminised papers or the negatives that used to be employed with them.

The negatives, it must be mentioned, were quite different in character from the present ones, and they had much to do with the stability of the old prints. This statement may possibly take some of our newer readers by surprise, but it is the fact, nevertheless. The early wet collodion negatives, it may be explained, were developed with pyrogallie acid, and they were made very strong, and often took, in a good light, a whole day or more to print. They differed entirely from dense gelatine ones, which although they may even take longer than the time mentioned to print, are really not anything like so intense, that is, in the sense the others were. The slow printing qualities of dense gelatine negatives is due to general density and staining of the film, and not to the long range of tones from the highest lights to the deepest shadows. The old negatives were exceedingly intense; the highest lights were very dense, while the deepest shadows were represented by perfectly clear glass—as clear, in fact, as if there was no film whatever upon it. Now a little consideration will show that during the long time the lights were in printing through, the light would be penetrating deeply into the paper in the shadows, which would become strongly bronzed through the large amount of silver that was reduced in them. It was no uncommon thing for the deepest portions of the image to show on the back of the paper. Hence the image was almost as much in the body of the paper as it was on its surface, so that the prints contained a large proportion of reduced silver to begin with, and, consequently, a larger quantity to resist the action of time than is the case with modern negatives, and prints from them where the image is confined entirely to the surface or albumen film. This shows that the permanence of the old prints owed much to the character of the negatives from which they were made.

Now let us consider the papers upon which the prints were produced. In the early days two were employed—the plain salted and the albuminised—which the user had to sensitise for himself, even if he had not to salt, or albuminise them as well. Here is a formula for the latter, taken from a third edition (1856) of "Hardwick's Photo-

graphic Chemistry":—"Chloride of ammonium or sodium, 200 grains; water, 10 oz.; albumen, 10 oz." Here it will be seen that the albumen was diluted with an equal bulk of water, and that the mixture contained no less than ten grains of chloride to the ounce. The paper thus prepared would now be classed as a matt paper. With the present albumen paper, not only is the albumen used without dilution, but it is often concentrated so as to obtain a high gloss, and also confine the image to the film of albumen as much as possible. The albumen now used also contains far less chloride than did that of fifty years ago. The early albumen paper was sensitised by floating it for from three to five minutes on a solution of plain nitrate of silver; strength, sixty to ninety grains to the ounce of water. Now it will be seen that the chloride of silver, formed by double decomposition, was not only on the surface of the paper, but in the body of it as well, and that there was also a very large amount of free nitrate as well, both in and on the paper. Hence, with the strong negatives just referred to, a very large quantity of silver was reduced to the metallic state in the formation of the picture. The modern albumen paper is but lightly salted and lightly sensitised, and is also printed from thin negatives, so that there is very little silver reduced as compared with the older paper when the image is printed. This shows the wide difference there is between the paper used in former times and now.

The conditions of toning and fixing then and now were also different, although the combined bath was the one employed. The old combined bath contained no such things as alum, acid, lead, etc.; it was simply a strong solution of hypo, water, and gold. Here is the formula that was generally employed:—Hyposulphite of soda, 8 oz.; water, 16 oz.; chloride of gold, 8 grains. Some workers used even a stronger bath than this, and some also added a little nitrate of silver as well as the gold. The toning action was slow—usually taking an hour or more. Here, then, there was no question—with this strong solution—about the prints being thoroughly fixed long before the desired tones, however warm, were obtained as there is with the present-day combined bath. By reason of the large quantity of silver reduced in the prints, there was a large proportion of gold deposited upon them in obtaining the tones, therefore the image, generally, was far more "robust" and better adapted for resisting adverse influences than is the present-day delicate and attenuated one.

There is yet another point that should be kept in mind, which is, that the work in the olden time was usually done by those who thoroughly understood it, and did it in a conscientious manner. That is not always the case at the present time, when so much of it is entrusted to lads and girl apprentices.

We have here very briefly pointed out the differences between the conditions under which silver prints which have lasted fifty years, and more, were made and those obtaining now. But can these conditions be assimilated in any way? The papers of old would certainly not be suitable for modern gelatine negatives, and, on the other hand, the old intense negatives would practically be useless with the present-day papers, which are specially made to meet the requirements of thin and delicate ones.

LENS RAPIDITY.

Amongst the many dogmas concerning matters photographic which have become classical through age and frequent repetition one is more venerable or more supported by authority than that which affirms that the rapidity of a lens depends upon the size of its working aperture. Were this in reality true the giving of correct exposures would be a far easier matter than is unhappily the case, and consequently manufacturers of plates and films would find the annual consumption of their goods considerably restricted. But, as a matter of fact, practically it is not true, as it merely covers one portion of the subject, and one portion, moreover, which I venture to assert does by no means the most important. It would be equally true and equally false, for example, to say that the efficiency of a lens depends upon the amount of cork put into their construction. As was proved by a recent appalling disaster, a good many things other than cork must be present, and must be serviceable, before the life-saving apparatus itself can be regarded as efficient.

In the following brief notes I propose to show not only that the universally-received belief that lens rapidity depends upon the width of the working aperture is only partially true, but also to point out what are the chief amongst the other causes which govern this condition.

It requires no special proof to convince even an expert photographer that, other things being equal, the greater the diaphragm opening of a lens the greater must be the amount of light capable of passing through it, and consequently the greater must that lens rapidity be. But, unfortunately, other things are not always equal, and light may lose a portion of its volume and some of its actinic properties during its passage through a lens, thus rendering the latter less rapid. This highly-important question, like all others, must, in fact, be considered, not from the ideal or theoretical standpoint, but from the actual and the practical. And in actual practice it will be noted that there exist a good many factors other than the lens aperture which considerably modify its "normal" rapidity.

In the first place, let us take the substance from which a good photographic lens is manufactured. In the making of the best optical glass certain minerals are employed, the selection, proportionate amount, mixing, heating, and cooling of which require great scientific knowledge and manipulative skill. So far, however, though it must be admitted that very great attention is bestowed on the several mechanical processes, scientific knowledge is not yet by any means commensurate with the end in view, and this deficiency leads to the production of lenses which sooner or later become discoloured through chemical action, in a slight or in a more pronounced degree. When this condition occurs, even when it is so faint as not to be apparent to the eye unless looked for with great care, rapidity is sensibly diminished, becoming more accentuated, of course, in proportion to the amount of discoloration present. On laying a lens afflicted with this form of constitutional malady on a sheet of white paper it will be seen that the glass is no longer absolutely white, but shows, on the contrary, distinct traces of yellow or brown. And, apart from this faint impairment of transparency, different degrees of "rusting" may make their appearance up to that which is clearly discernible and obviously harmful.

But instead of the discoloration being uniformly diffused throughout the glass, it may be present only in scattered spots or in the form of striae, conditions which, although for mechanical reasons not so fatal to rapidity, yet undoubtedly slow the action of the lens.

Similar in some respects to chemical spots are the air-bubbles so often found in the substance of lenses, good, bad, and indifferent. When they are minute and few they are practically

innocuous, but when they are many and large they cannot be regarded otherwise than as elements detrimental to rapidity. In saying this I am not only supported by my personal experience, but by what is of far greater weight, the authority of a well-known law of optics, although I am perfectly aware that during recent years many of the foremost manufacturers, finding they were unable to produce the best class of photographic glass, perfectly homogeneous in structure, have issued notices to their clients stating emphatically that the presence of bubbles is quite unimportant. When, however, they have sufficiently improved their methods as to eliminate these deleterious air cavities, I feel confident the most successful in this direction will instantly circularise the purchasing public against buying lenses which are not entirely free from bubbles. Human nature is made that way. So also, and apart from the glass of the lens, obscuration may, and often does, occur through uneven dessication of the so called cement with which the separate portions of a lens component are fastened together. This is usually due to exposure, to rapid changes of heat and cold, or to great variations of humidity, even when the best—i.e., the most suitable—material is employed, but is also often caused by the use of cement of inferior quality, or to improper handling during the process of manufacture.

Passing now from the substance of the lens to its surface, we find further and fruitful sources of lessened rapidity. In the first place, the accumulation of dust and the products of moisture, if not carefully prevented and removed, are common and exceedingly potent causes of this condition. In many hand cameras the lens cannot be taken out for purposes of cleaning, except with great difficulty and much risk of doing damage, and thus the dust demon has ample scope and leisure for working his wicked will. So also not a few otherwise high-class lenses are so constructed that their components cannot easily be taken asunder, and on the inner surfaces of these fine particles of dust readily collect.

Then, again, and in addition to or apart from the above-mentioned conditions, a very frequent source of lens-dimming is seen in the case of numerous patterns of hand cameras which have no protecting cover, or no adequate one, over the front surface of the lens when carried ready set for use. For instance, I have just received an expensive folding "Post-card" hand camera, the lens of which is without a vestige of cover both before and behind. In carrying such an instrument along a road, or, indeed, in any situation out-of-doors, it would be quite impossible to keep the anterior surface of the lens bright and free from dust. In the case of the numerous types of "Reflex" cameras which are now deservedly coming to the forefront of popular favour, the release of the shutter acts like a powerful fan, and creates an air-blast, setting up a miniature storm of dust, much of which eventually settles on and greatly obscures the posterior surface of the lens.

Several other factors making for obscuration, and, therefore, for diminished lens rapidity, could be readily adduced were it necessary to advance further evidence in proof of my contention. But sufficient has, I think, been said to show that the mere width of the working aperture of a lens is by no means in practice the sole factor governing rapidity, or, as I believe, the most important one. The working aperture of a lens can always be ascertained with facility, and the necessary calculations as to exposure are easy in the extreme. On the other hand, many of the conditions I have referred to are not only extremely common, but are difficult to detect, and still more difficult to rectify; some vary greatly in their intensity, it may be, from day to day, whilst others, from their very nature, are wholly irremediable.

From the foregoing considerations the following amongst other practical deductions may be made:—

1. Every lens and every camera ought to be so constructed

that the former can be readily removed and taken apart in order to be cleaned in every portion.

2. Every camera—more especially every hand camera—ought to have the front surface of the lens thoroughly protected from dust and moisture.

3. No lens can be regarded as efficient which is not perfectly white when looked at by transmitted light; which has not a brilliantly-polished surface, and the substance of which is not free from marks, cavities, or other departures from homogeneity.

F. GRENFELL BAKER.

STEERAGE PHOTOGRAPHY.

BY A THIRD-CLASS PASSENGER.

The photographer has one peculiarity which marks him as a man apart from the common run of mankind. Whereas the average man, in those too-brief periods of his life known as "holiday" aims to forget his normal existence and the daily grind that brings him bread and cheese, the photographer celebrates a holiday by seizing his camera and making for new scenes which he may portray.

There is no doubt about it, the photographer is generally in the profession because he loves the work, and has found the niche for which he is fitted. Outside of business days he takes his hand-camera, and becomes a "blooming amateur." Thus it seemed natural to sprawl on a tarpaulin-covered hatchway, and listen to the photographer who had left his business for a month's holiday—happy mortal!—and to hear him wax eloquent as to the merits of his pocket kodak. His sleeping berth was shared with fifteen others, and all through the day there would be six or eight men sprawled in their bunks; but in that berth he developed his negatives, for his enthusiasm was such that he could not wait until the boat reached New York. And yet he was a professional photographer!

I had noticed him prowling along the steerage deck. The promenade deck above him cut off his light, and prevented any chance of work. For his pocket-camera was incapable of any effort better than F. 11, and that aperture is hopeless under cover and on dull days. But before we were two days out he was marching up and down with a strip of half-a-dozen negatives flapping in the wind. He had managed to find subjects which his camera could compass.

The man who goes a voyage for several days' duration should certainly take a camera with him. There are lots of interesting "bits" to be snapped, when the first forty-eight hours are over, and passengers are struggling on deck to get the last traces of "that unwell feeling" blown out of them. And the camera should be a hand one. The space is often too crowded for comfortable tripod work, and the whole charm of ship photography lies in its naive spontaneity. A happy snap makes a pleasant picture; but any attempt to pose subjects has disastrously wooden results.

First and second class passengers have usually facilities for changing plates; and if they really wish to develop plates the way may be made easy for them. But if the steerage passenger wishes to develop—well, he will need a strong dose of enthusiasm to carry him through. Make sea photography a holiday pastime, and be content to take it in moderation. If they are not recklessly wasted, a dozen plates will give a very fair record of a voyage from Liverpool to New York. Of

course an inexperienced photographer will waste plates on Fastnet Light, as the ship slips between it and the Irish coast, or on the coast itself, or some sailing-ship which passes a mile away. But outside the ship, if we except a snap at gulls which come screaming after the waste from the table, there is usually nothing to photograph.

The inside economy of the ship is equally unsatisfactory to the holiday photographer. Artificial light would be a necessity; but the real drawback is the bareness and crampedness of all below decks. Narrow passage-ways, close-packed sleeping-berths, and bare wooden tables and forms are about all that is to be found in steerage quarters, and in the more expensive parts the prevailing impression is red velvet and polished mahogany. Yes, except for one or two views along the deck, ship photography is a matter of snapshots of life.

There were four photographers on the steerage deck. First, there was our professional enthusiast, with his pocket kodak; second, a young schoolmaster with a No. 2 Brownie; third, a young clerk with a quarter-plate magazine camera; and, last, there was your servant the writer.

No two ships seem built on quite the same plan, but of all of them I believe that steerage passengers have some share of the deck open to the sky. On some of the best-known of the Atlantic liners the open space is very limited, being confined indeed to a hatchway on which passengers can sit or sprawl in the sun. We were more fortunate than this, for we had not only two hatchways, one each forward and aft, but we had also a few square yards of open deck between the hatchways and the bulwarks. These open spaces were our photographic salvation. Sometimes a picturesque group of Hebrew women washed tiny garments, or hung them in the sun; sometimes an old Hebrew would don his phylactery and rock himself to and fro at prayers. Or a group of stewards and firemen would stand to catch the breeze. There was always some life under the open sky, and always the possibility of an interesting picture.

I have recommended that the camera should be a hand one. Either films or plates may be used; and if the latter, there is no real difficulty in changing them. The electric light can be switched off for a few minutes—it is safer to detach the lamp, rather than just switch off the light—and then under a blanket it is easy to do the rest. I would certainly not counsel development on board. If, however, enthusiasm prevails, borrow a pail of water from the steward, and work under blanket as before, using developer which was mixed before the trip. Perhaps the steward has a spare room which may be used—and third-class stewards are usually good-hearted, and do not expect enormous tips. A sailor will always tell you which tap yields salt water (fresh water does not run to waste on board ship), and salt water is all right for (photographic) washing purposes.

It is when we near land that the photographer is in his glory. He has picked up stray subjects on board ship; but he is just a little tired of the trip, and he longs to step on firm ground once more. Instead of seeing one ship per day, three are in sight at one time. Then he sees that faint line of land to the north. After this events crowd thick and fast. There is a pilot to be picked up; the shore grows nearer and nearer until fields, and houses, and lastly people, can be seen. More boats pass, and we watch them in our finders to decide how big they would be on the plate. There is always plenty to see when slowly steaming up a crowded harbour, and everything looks doubly alluring after a week at sea. On board ship we had felt that the photographic limitations were too many; but as we swung alongside the dock, and expended a last plate on the bare height of a New York skyscraper, we felt anew the force of the rule—never travel without your camera.

PLATINUM PRINTING, BRONZING, ETC.

The making of platinum prints during the summer season is almost always attended with more or less trouble. These difficulties are not entirely due to the high temperature, but arise in a great measure from the excess of moisture contained in the atmosphere. This moisture, aided by the high temperature, causes the ferric salts employed in the preparing of platinum paper to become very active, and tend to produce other salts of iron by oxidation. This action is the main cause of the yellowing of the whites of platinum prints. Bronzing occurs principally through over-exposure, causing an excess of ferrous salt to be formed from the ferric salts upon the paper, while this excess of ferrous salt in turn causes an excess of platinum to be deposited when brought into contact with a free oxalate, which is always contained in a platinum developer. The high temperature aids rapid development, and consequently results in excessive bronzing. This effect of bronzing is produced only with papers containing the iron salts in excess, as well as the platinum salts in combination therewith, because bronzing never occurs unless there is an excess of platinum deposited, and this, too, when deposited very rapidly, the rate of deposition having something to do in producing the bronzing effect. Such papers as the above are capable of producing the very finest results, because there is a sufficiency of both the salts of iron and platinum to give the required deposit before the sensitive surface becomes washed off the paper.

Mr. A. J. Jarman, in the current issue of "Wilson's," deals with these matters very fully. He says: "It is very remarkable that prints produced by the hot bath process, which process preceded the cold development process at present largely in use, showed very little tendency to while a print that was over-exposed became grayed all over, so that it was quite useless. This result was due, without doubt, to the sensitive surface being prepared quite differently to the present cold development paper and to the use of a perfectly neutral solution of potassium oxalate as a developing agent. Much greater care had to be bestowed upon the use of platinum paper for hot development than is exercised to-day in the use of paper for cold development. Every print had to be placed in a specially made tin case charged with dry calcium chloride, in a receptacle fitted beneath a perforated plate, which formed the bottom of the tin case, upon which the exposed prints were placed and kept as near air-tight as possible until the time for development arrived. Many photographers to-day employ simply a plain solution of potassium oxalate to develop prints that are made upon the present paper for cold development, and by this means very often get inferior results. This is because the potassium oxalate used varies in quality. If it is in the least alkaline the full values contained in the negative are lost in the print. An acid developer is best suited for cold development, restrained by the addition of either potassium phosphate or sodium phosphate, it matters not which, if the salts are mixed and the developer made up at once with hot water. If sodium phosphate is mixed with potassium oxalate and kept some time before use, the combination becomes moist and forms a conglomerate mass. This, however, is no detriment when made up into a developing solution. This moistening of the salts does not take place when the potassium phosphate is used. When making up a developing solution for cold development the salts should always be dissolved in boiling water, so as to secure a more perfect combination, the resultant solution being filtered for use as soon as it becomes cold.

The best way to make up a platinum developer is to employ a stoneware crock of any kind, with a lid. The salts may be placed therein and the necessary quantity of boiling water

poured upon them from a tea-kettle, stirring the whole with a clean glass strip. An excellent developer for black platinum prints can be made as follows:—

Potassium Oxalate	6 oz.
Sodium Phosphate	1½ oz.
Oxalic Acid (c.p.)	½ oz.

Place these in a stoneware crock, then pour upon them fifty ounces of boiling water. Stir well, then allow to cool, when it is ready for use.

In the process of platinum printing there are sure to be some prints that have been overdone, or, as it is usually termed by platinum printers, "cooked too much." It is with this class of print that this article is intended to deal. Generally such a print is torn in halves in the printing frame and thrown away or cast into the waste-box. If such prints are only over-printed they would not make a good picture under the usual method of development, they may be saved and excellent pictures made by developing them in a specially prepared developer. It is this class of print that yields the objectionable bronzing in the shadows, and is so often thrown out as being unfit for delivery. This occurs only too often with very large platinum prints, such as 11 by 14, and 20 by 24, which, owing to the high cost of the paper, becomes a serious loss to the photographer. All such prints as these should be placed in a separate box or receptacle until the time for development has arrived. Then have prepared and ready at hand a developer made up according to the following formula, which, after being prepared and allowed to become quite cool, filter twice through absorbent cotton, being particular at the same time that the glass funnel and the bottle or bottles into which it is filtered are perfectly clean:—

Potassium Oxalate	8 oz.
Potassium Phosphate	2 oz.
Oxalic Acid (c.p.)	1 oz.
Chloride of Potassium (c.p.)	2 oz.
Boiling Water	60 oz.

Stir well, allow to cool down for half an hour, then add glycerine, 8 oz. Stir well until all are thoroughly mixed. Allow this to become quite cold before use. Employ a separate tray for this developer, and place a small lump of ice in it a short time before use. Take one of the overdone prints and pass it through the developer in the usual way. It will be seen to come up very even. As soon as development has been carried to the necessary point, place it at once in the acid-clearing solution, 1 part muriatic acid to 60 of water, the same as is usually employed. After a few minutes remove the print and examine it, when it will be found to be perfect in every particular, with a full colour, inclining to blue-black. Of course, if the print has been hopelessly overprinted, then it must be discarded, but for prints that are somewhat overprinted and would otherwise be completely spoiled and bronzed in under the usual method of development, all and every such print can be saved and turned to profitable account by the employment of the above developer. This solution can be used over and over again, the same as an ordinary developer, taking care to filter each time before use, and adding a little clean new developer each time.

In the formula given for the first developer as much as one ounce of oxalic acid may be used, for by the use of this chemical in moderate quantity the whites are kept very clear. This is brought about by the dissolution in the developer of the traces of the lower oxides of iron formed by damp and heat, so that by keeping the whites brilliant and clear the blacks appear to be more black. More than this, a strongly acidified developer, like those of green hue, clears away the very cause of the yellowing of the whites of platinum pictures. It may be taken

as an axiom that the thicker or heavier the paper is, the longer it must remain in the acid clearing solutions, so as to clear out every trace of the iron salts. The writer had considerable trouble some six years ago in keeping the whites brilliant when using a very heavy platinum paper, but succeeded in getting over it by leaving the prints in a fourth acid clearing bath overnight, washing them the next day. Under this treatment the whites were found to be all that could be desired. This proves that "time" is necessary to clear out the iron salts absorbed by a heavy paper. As to the clearing solution of muriatic acid or, more correctly, "hydrochloric acid," this solution is almost universally used. There are other clearing solutions, that which was employed originally was oxalic acid, and of the two is superior to hydrochloric acid. The drawback to its use is its great danger of poisoning the fingers by absorption, its tendency to become lodged under the finger-nails and around the quick, producing intense pain, throbbing, and eventually a small fester. An excellent plan to adopt after the hands have been dipped for some time in an oxalate developer is to rinse them well in clean water, using no soap, then rub the hands well with lime-water. The lime neutralises the oxalate, and thus prevents the chance of poisoning.

The introduction of chloride of calcium and chloride of sodium into the clearing solutions has a very marked effect in preserving the whites of the picture. The following clearing solutions for use during the hot weather are very effective and certain in their action:—

Sulphuric Acid (c.p.)	2 oz.
Water, Cold	120 oz.
Chloride of Sodium (Common Salt)	2 oz.

Pour the acid into the water, rinse out the graduate, place the salt in the tray, stir until it is dissolved, and mix. As soon as the print is developed, place it in this bath. The iron salts become quickly dissolved out; in fact, this mixture produces hydrochloric acid in its nascent state. This appears to account for its decided action in the clearing, because all bodies become more active when in the nascent condition, or, in other words, when in their highest active state. Another excellent clearing bath the writer has employed with perfect results is made up as follows:—

Hydrochloric Acid (c.p.)	2 oz.
Water	120 oz.
Chloride of Calcium	2 oz.

The chloride of zinc and magnesium do not give the same results, the chloride of zinc having a tendency to make the hands sore, but the chloride of calcium acid bath is very good.

Sometimes it occurs in the process of ordinary development that a print otherwise good is too black and undefined in the shadows, although it has not reached the stage of bronzing. The print may be a valuable one, and wanted in a hurry, at the same time, owing to bad weather, there is not an opportunity to make another print. As every photographer is not equipped with an electric-light printing plant, it may prove both profitable and advantageous to save such a print. This can be accomplished in a very simple manner. The question has often been asked, and is still asked, "Can an overdeveloped platinum print be reduced?" It can be reduced, and accomplished very effectually, not by chemical means, for it is impossible to dissolve platinum by any chemical agency when deposited upon paper without destroying the support. But the reduction can be made mechanically, and in a very simple way, especially if the print has not been allowed to dry from the time it has been developed, cleared, and washed. The paper is then very pliable, and the platinum image is held by slight tenacity to the surface. If the print has been allowed to become dry it must be well wetted and allowed to soak for some time, say an hour, before reduction is attempted.
